COCOS PLUMOSA PALMS. A MIDWINTER SCENE IN SOUTHERN CALIFORNIA.

Cocos Plumosa

Nothing so impresses the stranger who visits California for the first time as the great wealth of tropical vegetation to be seen along the older residence streets, the chief glory of their dignified, majestic appearance, their dignified, majestice appearance, coupled with a grace and elegance that might well be termed royal, the palms have been called the "Kings and Princes of the Vegetable Kingdom." While we may grant the truth of this appellation in general there certainly should be queens where there are princes and the title of "Queen of the Palms" is an honor to which Cocos plumosa is indisputably entitled.

Throughout a trial extending over more than a score of years, Cocos plumosa has proven peculiarly adapted to our soils and climate. In luxuriance of growth and grace of habit this palm is unsurpassed and adds more of a tropical touch to our gardens than any single plant we grow and on this point is only surpassed by a huge clump of rank-growing well-cared-for bananas. Cocos plumosa hails from central Brazil and is sometimes confounded with C. Romanzoffiana from the more southerly parts, a palm stiffer in habit, slower in growth and with smaller parts. In general appearance it has not that bold, rampant growth which is the chief landscape charm of the Cocos plumosa. This palm is peculiarly easy of cultivation and thrives marvelously well in all the more favored parts of the state. In San Diego there is a truly royal group surrounding the small plaza in the central part of the city and many fine specimens in private grounds. In and about Los Angeles they may be found in profusion and nowhere do they grow with greater rapidity or more luxurious foliage. Scores of fine specimens might be listed that are worthy of a visit by all plant lovers. Up in Santa Barbara, both in city and county, they have been planted everywhere; much more universally than elsewhere in the state. Many city blocks may be found where they are used as street trees and nothing used for the purpose has such a softening influence upon the harsh, monotonous lines of curb and sidewalk as has the foliage of this truly royal palm.

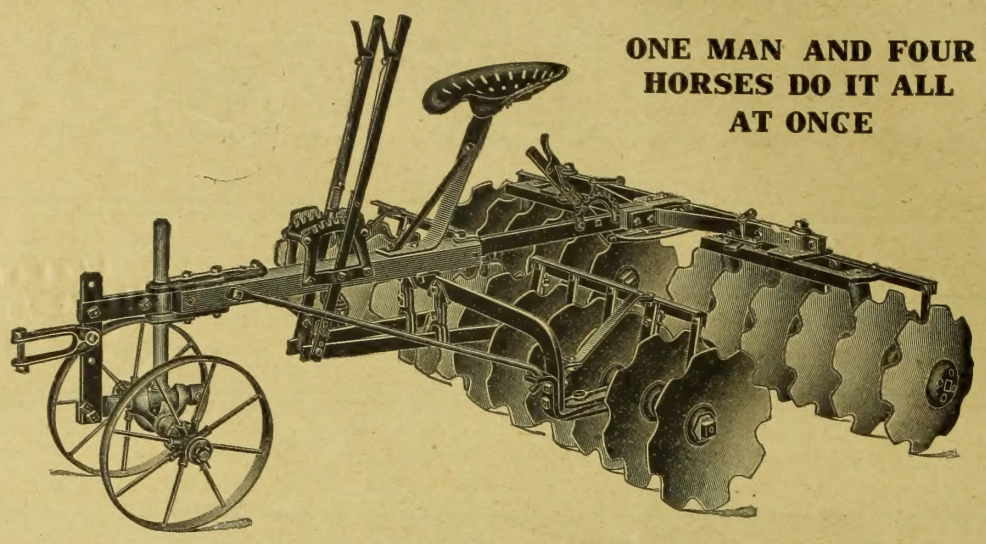
ARNOTT DOUBLE DISC HARROW

A Plow—A Disc—A Pulverizer—A Smoothing Harrow all in one

The SENSATION of the Day

Compare it Point for Point With Any Disc Harrow Made

Double Gangs
Double Cut
Double Throw
Double Levers



ONE MAN AND FOUR HORSES DO IT ALL AT ONCE

The flexibility of the **Arnott "Double-Cut"** in contrast with the stiff action of other two-way harrows is what is making it so popular. This flexibility is possible because of our Universal Joint connecting the front and rear gangs. For lack of this feature other double harrows have a good deal of side draft and will not make a square turn without digging a great hole. This can't happen on the **Arnott.** Independent front and rear levers within easy reach of rider.

Squirrels Bring Death and Financial Loss

Address of Dr. Rupert Blue before the State Fruit Growers Convention at Stockton, in which the Investigations into the Work of the Squirrels is Emphatically Told

The extermination of squirrels has become one of the serious problems of this state. The interest in the subject prior to 1907, was almost wholly an economic and financial one. Since that date evidence has been collected which proves that this animal is responsible for the transmission of plague and the chief source of its continuance in this country. As a result, the sanitarian has become interested in the natural history of the ground squirrel, and has joined hands with the economic interests in the war of extermination.

A statement of the annual losses due to these animals should not be necessary. In a recent paper, Dr. Merriam, of the Biological Survey, stated that they inflict injury on all classes of crops, and rank among the most destructive of our native rodents. The amount of annual loss to agriculture was given as $10,000,000. This we can readily believe in view of their wide distribution and great numbers on the Pacific Coast. It is time for us to consider another aspect of the problem, namely, the sanitary importance of the rodent species. The following pages contain a brief review of the field work and an outline of the infected area.

Report of Field Operations.

As far back as 1903 Bubonic plague was suspected to be present among the ground squirrels of California, but every effort made to confirm this as a fact failed until the summer of 1908 when in Contra Costa county, four naturally infected ground squirrels were found. Investigations which followed during the fall of 1908 and spring of 1909, disclosed the presence of a rather widespread epizootic, and in April, 1909, a well organized campaign was inaugurated for the purpose of determining the extent of this infection, and to evolve, if possible, a plan for the destruction of squirrels found within the infected area. This date, April, 1909, marks the beginning of systematic work, and in the early part of the campaign operations were confined to the counties of Contra Costa and Alameda, contiguous to San Francisco Bay.

It may be suggested in passing that since that date there have been received from these counties up to November 5, 1910, squirrels as follows: Contra Costa county, 32,318; of which 247 were infected; human cases during same period, 3.

Alameda county, 9663; infected, 83; human cases during that period, 2.

In order that one may not be misled by the comparative number of infected squirrels herein reported, I should state in advance that while the percentage of cases of infection found represents roughly the comparative degree of infection in the various counties shot over, it is not to be regarded as representing the total amount of infection present, since the work was undertaken primarily to determine the limit of the zone of infection, and in the majority of cases hunting operations have been pushed into new territory upon the finding of a positive focus.

In October, 1909, infection among the ground squirrels had been found so widespread in Contra Costa and Alameda counties, that scouting parties were sent farther south and east into Santa Clara, San Joaquin, Stanislaus and Merced. Three weeks after this advance into new territory infection was found in Santa Clara and San Benito, and as a result of subsequent work up to November 5th of this year, twenty-three infected squirrels have been found among 7286 received from San Benito. During the above period there has occurred in each of these counties a case of human plague, in each instance the disease arising in communities known to harbor infected squirrels.

In November following, just one year ago, it again became necessary to push the work farther afield, and the skirmish line was extended to include Santa Cruz, Monterey, San Luis Obispo, Santa Barbara, Ventura, Fresno, Tulare and Kern counties. A few weeks after this advance was made infection was found in Santa Clara county, and at the end of the year, December 31, 1909, infection among ground squirrels was known to exist in five counties, namely: Contra Costa, Alameda, Santa Clara, San Benito and Santa Cruz. Since this date work has been continued, from time to time, and on November 15th, just passed, there have been received and examined from the counties named 72,208 squirrels, eight of which proved infected: three from Santa Clara, four from Monterey and one from San Luis Obispo. It is of interest to note, in passing, that over ten thousand squirrels had been examined from Monterey county before the first case of infection was found.

The number of squirrels received from the various counties is: Santa Cruz, 1,673; Monterey, 22,855; San Luis Obispo, 18,635; Santa Barbara, 4,767; Ventura, 2,354; Tulare, 6,442; Fresno, 15,143; Kern, 339; or a total of 72,208.

In January, 1910, realizing the danger residing in foci of squirrel infection scattered immediately beyond the bay cities of Berkeley, Oakland and Alameda, the creating of a squirrel free zone around these cities, as a protective measure, was decided upon, and a squad of men, in charge of an inspector and under the immediate direction of a foreman, began squirrel eradicative work. A point of the bay just north of the city of Berkeley, on the county line, was selected, and following the county line from the point of origin to a point just north of Fruitvale, a belt or zone averaging one mile in width has been made practically squirrel free. This work has continued without interruption and a vast territory has been covered. Shortly after the work was undertaken two foci of infection were found within the limits of this zone—a stone's throw from a suburban home, and later, during January, February, March and April, a total of 22 infected squirrels were found within the northern end of this belt. When it is remembered that this zone just skirts the inhabited portions of these cities the importance of the work can be appreciated.

Apparently San Mateo county has remained free from infection, for nothing of a suspicious character has been noted after an examination of over 3000 squirrels, but as a precautionary measure, pending the further examination of the rodents infesting this county, a squirrel free zone averaging a mile in width, extending from the bay to the coast, just below the San Francisco county line, has been thrown across the peninsula. It is believed this barrier if maintained squirrel free, will effectively prevent the introduction of the disease into San Francisco county, should infection subsequently develop in San Mateo county.

In the spring of this year work was again undertaken in San Joaquin, Stanislaus and Merced counties, resulting in the finding of infection in all three counties, five in San Joaquin, five in Stanislaus and three in Merced, all west of the San Joaquin river.

From these counties we have received: San Joaquin county, 10,020; Stanislaus, 2,012; Merced, 11,658.

Later in June squirrel shooting was extended to include a portion of Southern California, and hunters have shot within the city and county of Los Angeles, and the adjacent counties of Orange, San Bernardino and Riverside. Specimens are still being obtained from Los Angeles county and to date over 12,000 squirrels have been received from Southern California, but without record of a suspicious case.

The totals from the South are: Los Angeles county, 8,591; Riverside, 1,096; Orange, 1,8544; San Bernardino, 606.

The statistics given, while representing the individual amounts of work done do not enable one to readily grasp the situation; the vastness of the work performed will be better appreciated by a short resume.

From the inception of the work until the 5th of November, there have been received and examined at the laboratory 173,717 squirrels. These have been obtained from 29 counties; 397 of the animals proved to be infected with bubonic plague, and were shot or found at widely separated points over an area embracing ten counties. During the same period of time eight cases of human plague have been reported, all having occured within the limits of the squirrel infected zone. (Human cases, Contra Costa county, 3; Alameda county, 2; Santa Clara county, 1; San Benito county, 1; Los Angeles county, (1908) 1, and in every instance there existed a sufficiently intimate association with ground squirrels to warrant the statement that the squirrel was the probable source of the disease. Several of these cases, fortunately mild, were diagnosed only after surgical interference—plague being a secondary consideration—and these should serve to place the practitioner on his guard; other cases may occur and remain unrecognized, and the possibilities, following failure to properly diagnose plague, can be appreciated only by those who have served throughout an epidemic of this grave disease.

In conclusion it may be said that the work just outlined, while extensive, is preliminary in character; localized squirrel free zones remain protective only while kept squirrel free; localized foci of squirrel infection may be destroyed, and temporary safety be secured, but just as surely will subsequent migration of the squirrels reinfect this territory. The squirrels over the entire infected area must be destroyed; the state of California must be made a squirrel free zone. Only in this way can we effectually remove this menace.

Remedial Measures.

The necessity for co-operation and organization in the work of squirrel destruction is fully appreciated. Without the assistance of the farmer, orchardist and land-owner generally, success will be impossible. With a view to securing the personal co-operation of property owners, a state-wide campaign of publicity and education has been inaugurated by the state health authorities. It is pointed out, in the literature issued, that the project should be taken up for the purpose of protecting the lives of the citizens and also to save the crops from destruction. The viewpoints of both the sanitarian and the agriculturist are thus considered.

A plan of campaign has been proposed which places the legal responsibility upon the shoulders of the county boards of supervisors. As they are the source of authority all official work should be done with their consent and co-operation.

It is the purpose of the health authorities, both Federal and state, to enforce the state law of March 13, 1909, called an "Act for the Extermination of Rodents." It is believed, however, that the land owner will willingly take up the work in view of the

(Continued on Page 23.)

100% PER ANNUM PROFIT

The West Riverside Estate (Inc.) owns 3500 acres, 5 miles west of Riverside, one of the wealthiest cities per capita in America.

500 acres of this is in 10-year-old full bearing navel orange orchard. These orchards are in A1 condition, have every possible advantage of soil and climate, and in addition have the cheapest and best water right in Southern California.

For the purpose of immediately attracting the attention of investors, in order that the estate might be most rapidly developed and settled, the company will, for a limited time, make the following offer:

The West Riverside Estate

(INCORPORATED)

Will sell you a 5, 10 or 20 acre 10-year-old navel orange orchard

In Full Bearing Now

With ample cheap water, located on the famous West Riverside Estate

For $1350 Per Acre

One-fifth, or $270, per acre cash at date of purchase.

Balance, which you should make from the crops, in eight equal annual installments.

Interest at 6 per cent., payable annually.

Deed with certificate of title at date of purchase.

NOTE.—The company reserves the right to advance the price after February 15, 1911.

Based on a 30-year record of Southern California's orange industry, this offer means that you can purchase an income property of established earning capacity on such terms that the property will pay for itself out of its own earnings inside the purchase time.

In a nutshell—you are offered an opportunity of investing multiples of $270 in a property worth $1500 for each $270 invested, that will in all probability pay for itself in four or five years, and then pay you 100 per cent. per annum net, or better, on your original investment.

The West Riverside Estate groves are the most highly endorsed and recommended citrus properties on the market today.

These letters are open for your inspection.

For sale by over 200 representative real estate firms or,

R. J. Widney

Citrus and Tropical Fruits

USE OF POTASH IN CITRUS GROVES.

The office of the Citrus Experiment Station of Riverside has been the gathering place for many who discuss scientific questions of horticulture, especially those of soil chemistry. The Cultivator gave some months ago liberal extracts from the debate on phosphoric acid. A similar discussion was recently held on the subject of potash. We quote from the report of the Riverside Press:

The speakers included J. H. Norton, the director of the station, who gave the results of experiments covering one year in the use of potash on Southern California soils, and E. S. Babcock and Fred M. Reed. Mr. Babcock discussed the scientific relations of potash to plant growth, and took up the geological phases of the question.

Mr. Reed cited the available sources of literature covering the subject of potash. In his remarks he called attention to an experiment made in this city with the use of potash that proved the inadvisability of drawing any conclusions from the apparent results of one year's experiments. For instance, the sugar content of the oranges in one grove was very materially increased one year when potash was used in liberal quantities. There was a decrease in the sugar content the following year, although potash was used, proving that the sugar content was not governed by the use of potash.

Hitherto Unpublished Experiments.

In his summation of results of fertilizer experiments on citrus seed beds during the year 1909, Mr. Norton used the pomelo, both sweet and sour stocks.

The figures were obtained by weighing all the plants of each plot, the time of transplanting, and taking an average of the three stocks. All figures have been reduced to percentages, using the check plot as 100.

Where the single elements were used the following results were obtained (check 100): liquid manure, 62; sodium phosphate, 84; nitrate of soda, 92; sulphate of potash, 97. There was a loss in every case from the use of the single elements, which was probably due to the fact that the use of a single element created a more unbalanced condition in the food supply for the plant than was in the original soil. However, it is to be noted that the loss from liquid manure was 38, sodium phosphate 16, nitrate of soda 8, while that of sulphate of potash was only 3.

"From the standpoint of pure mathematics," said Mr. Norton, "we would naturally think that while each of the elements gave a loss, any combination of these elements would also give a loss. But such was not generally true. On the contrary, it was the exception, and in every exception liquid manure had been used, which seems to say that the manure was responsible for the loss. And yet the loss in these cases was not nearly as great as where the manure had been used alone.

"After using potash in combination with each of the three elements above, the following yields were obtained: Manure and potash, 88; phosphate and potash, 119; nitrate and potash, 123. From the mathematics known to me there is no way of calculating the amount of gain which should be credited to each of these elements.

"Where the elements were used two at a time, not including potash, the following results were obtained: Nitrate and manure, 94; phosphate and manure, 106; phosphate and nitrate, 100. On adding potash to each of these combinations, the following were the results: Manure, phosphate and potash, 94; nitrate, phosphate and potash, 113; nitrate, manure and potash, 119. This gives a gain for the potash in the last two figures and a loss in the first.

"Nitrate, manure and phosphate gave a yield of 83, while nitrate, manue, phosphate and potash gave 82."

Results With Alfalfa.

Mr. Norton also gave a summary of the results of a year's experiments with alfalfa. All calculations were made in percentages with the check as 100. The yield of the check plot was 100; the sodium nitrate plots, 117; the super-phosphate plots, 118; the sulphate of potash plots, 129. The gypsum plots were found faulty, because of grass getting into the plots and for that reason no figures on the purely gypsum plots are given. While each of the three elements gave a decided gain over the check plot, it is to be noted that the potash plots were decidedly superior to the others.

The plots in which potash was used in addition to each of the other three elements, gave the following results: Nitrate and potash, 126; gypsum and potash, 134; phosphate and potash, 135. In a way these figures are similar to the corresponding figures on the seed bed, in that the benefit derived from the use of the two elements is not the algebraic sum of the results of the elements used singly. In these figures the result of the two is not the sum of the two used singly. A marked benefit was derived from all combinations by the use of potash, with the exception of the case of potash added to nitrate, and it is doubtful whether nitrate has an economic use in this climate on leguminous crops.

Where two elements were used, not including potash, the following results were obtained: Gypsum and nitrate, 115; gypsum and phosphate, 116; nitrate and phosphate, 119. On adding potash to each of these three combinations the results were as follows: Gypsum, nitrate and potash, 128; gypsum, phosphate and potash, 136; nitrate, phosphate and potash, 121. Again, the lowest yields were obtained where nitrate had been used, yet in every sense the addition of potash gave an increase over the plots without potash.

Gypsum, nitrate and phosphate gave a yield of 121, while potash added to to the above gave a yield of 122.

DRINK THE JUICE.

All of the famous hostelries in the world now serve their oranges in the form of orange juice, instead of furnishing the fruit itself. This is done for several reasons.

In the first place, sweet orange juice is sweet orange juice—it all looks alike, no matter whether it comes from a "nigger head russett" or an "extra fancy." Everyone knows

that the russett orange is sweeter and juicier than the bright, as a usual thing, but its appearance is against it, while the fancy bright orange sells mainly on its looks.

In the second place, the cleanly way to eat an orange at the table at least, is to drink the juice from a glass, instead of spattering it all over everything within reach.

Sherry, Delmonico, Hotel Astor, The Knickerbocker, The Plaza, The Waldorf-Astoria, The Belmont, and all the other strictly first-class establishments in New York City now serve oranges exclusively in this way.—Fruit and Produce News.

WARS OF THE INSECT WORLD.

So far, from personal observation, I have found that the grasshopers are by far the most irritable class of insects among themselves. They seem to enjoy fighting better than eating, and frequently fight until each has lost one or more limbs, and sometimes even until one succeeds in killing the other. So great is their interest in these deadly battles that they will allow themselves to be picked up and carried about, continuing the conflict in one's hand in the most unconcerned manner imaginable!

The katydids constitute the less quarrelsome members of the grasshopper family. Their fights are far and few between, but extremely violent when once started. I remember vividly a battle between two of these insects which I witnessed several years ago. It happened close to the edge of a small patch of woodland where several trees had been cut and the stumps left standing from two to three feet above the ground. To the top of one of these stumps a large katydid and his mate had crawled, perhaps to enjoy their honeymoon. As I stopped to watch their actions for a minute, a third katydid, seeing the happy couple, and feeling somewhat jealous, shrieked an insult to them from a near-by stump. The offended insect never uttered a sound, but, leaving its mate, flew directly to the other stump, where a fierce conflict ensued, ending only when the insulting one had been torn to pieces by his more powerful rival, much to the satisfaction of the female katydid!—Paul Griswold Howes, in Harper's Weekly.

GUAVA.

Dr. Franceschi of Santa Barbara writes as follows regarding the old favorite, the guava:

"Psidium Cattleyanum, ordinary "strawberry guava," well known to everybody in California, once supposed to be a native of China, because from there introduced to England, but afterwards recognized to hail from South or Central America, like all other kinds of guavas, is now planted in Southern California probably more widely than in any other country. It grows so freely, it is not affected by any disease, it bears so profusely, that it is no wonder that one sees it everywhere, in extensive ranches and in small city lots. Everybody likes the fruit, and more so the jelly which is made of it in immense quantities. The 'yellow strawberry guava,' Psidium Lucidum, introduced by the writer some years ago, looks very much like the first-named, but its fruits are yellow and generally of finer flavor. Psidium Araca has larger and thicker leaves, also larger fruits than the two preceding, of yellow color and of superior taste. Several other kinds of guavas are now on trial in the grounds of the Southern California Acclimatizing Association at Montarioso, Santa Barbara. The so-called 'lemon guava,' Psidium Guajava, very like the first kind ever introduced to California, is very seldom met at present, its fruit not being much liked, and possibly also for the reason that it happens to be severely attacked by "black scale," from which the above-named kinds are completely immune."

WHITE FLY INVESTIGATIONS IN FLORIDA.

Prof. R. S. Woglum, of the United States Bureau of Plant Industry, who has for some time past been conducting experiments in fumigation at Whittier, Cal., is now in Ceylon for the purpose of consulting with E. Ernest Green, one of the world's authorities on the group of "Aleyrodes Citri," the white fly. Prof. Woglum will next proceed to India, which is supposed to be the original home of the white fly, to study conditions, and if possible to find a parasite or active enemy to this pest to the end that it may be introduced in Florida.

Dr. Black, of the Government "Whitefly Station" at Orlando, Fla., is at present on a trip to Mexico and Cuba, searching for possible natural enemies.

In a recent letter from the Department of Agriculture, it is claimed that good results have been reached in the suppression of the whitefly by experimental and demonstrational spraying during the past season. Florida growers are warned not to be too much encouraged over the prospects of securing natural enemies of the pest. There is a possibility that either Prof. Woglum or Dr. Black may succeed, but the probabilities are against it. The Department agrees that the work for the final destruction of the fly is worth while, and is preparing to continue the search.—Florida Fruit and Produce News.

CITRUS CONVENTION REPORT.

The Proceedings of the Thirty-Seventh Fruit Growers' Convention, the Pomona citrus growers meeting, which was held under the auspices of the state horticultural commission in September, has been issued from the office of the commission and gives all the addresses and practically the entire discussion at that great convention. We say "great convention" because both in numbers and in accomplishment we believe it was one of the most important conventions ever held in the state. Over 600 people were in the hall at the time the gavel fell and at other sessions nearly 800 were in attendance. At the meeting committees were appointed to take up the matter of securing experts from the Department of Agriculture at Washington to investigate the decadence of citrus trees. The report may be had by addressing J. W. Jeffrey, State Horticultural Commissioner, Sacramento, Cal.

ORANGES AS FOOD.

Oranges are better than drugs for certain ailments. They act on the liver and bowels and nourish the body as well as furnish organic salts. It is said that one can live on an exclusive orange diet for months, for the fruit is rich in values. It has 11.57 caloric power to the ounce; 70 organic salts; 11.54 sugar and starch; 20 oil and acid and 82 protein.

LARGEST CITRUS NURSERIES IN THE WORLD

Parties contemplating the planting of citrus groves this coming spring will do well to send for our prices soon, as there will evidently be a shortage of strictly first class stock. Write today for particulars, or, better still, pay us a visit so that we may be able to show you just what we have.

Our finely illustrated booklet, "Citrus Fruits," covering the industry from the seed to the market, mailed to any address on receipt of 25c in stamps.

FLORIDA SOUR ORANGE SEED.

Put in your orders for Florida sour orange seed before the first of the year and be sure of getting your seed. We are collecting personally our own seed. A deposit of one-half required. Address OTIS E. HYDE, 1314 West 51st St., Los Angeles.

A RECORD-BREAKING OUTPUT.

With a twenty-million-dollar crop of oranges and lemons marketed and to be marketed, California has reason to be proud of its greatest fresh fruit industry, which has sprung into existence within the last third of a century. In 1891-2 the state only shipped 4,016 cars. Up to 1896-7 it only reached 7,350 cars, but the next year, 1897-8, doubled that output. By 1900-1 this was increased to 24,100. From that time on to this year the increase has not been regular, but in 1908-9 the output reached 37,091. This is from the entire state, and is constituted of 150 cars from the Sacramento-Placer county section, 400 cars from Butte county, and 2,380 cars from Tulare county. The balance, 34,450 cars of oranges and 6,800 of lemons, is from Southern California. The total output of the different districts will be as follows:

Locality.	Carloads.
Riverside district	4,650
Redlands district	4,600
Pomona district	4,000
Ontario-Cucamonga	3,650
Azusa-Glendora	3,500
Highland district	2,000
Covina	1,650
Fullerton-Placentia	1,300
Orange	1,200
Rialto	1,100
Alhambra-San Gabriel	1,000
Corona	950
Duarte-Monrovia	800
Whittier	650
San Fernando	550
Tustin-Santa Ana	500
Colton	450
Ventura county	450
Glendale	270
Anaheim	270
San Diego county	250
Moreno	175
Bloomington	175
Hemet	70
Other localities in So. California	240
Total	34,450
Tulare county	2,380
Butte county	400
Sacramento-Placer	150
Total north of Tehachapi	2,930
Grand total for state	37,380

The estimate of Mr. B. A. Woodford, general manager of the California Fruit Growers' Exchange, is given in the Riverside Press as follows:

From information as we gather it from all sections, the citrus fruit crop this year is much larger than that of last season and somewhat larger than that of two years ago.

From the best information that we can get, the crop of the entire state will aggregate this year around 45,000 cars, of which 6,500 will be lemons. Should the season be favorable, with no losses from wind or frost, and sizes run medium to large, we think shipments will be in excess of 45,000 cars. Should the reverse condition be true, and the loss of fruit in carloads shipped be considerable through damage and through small sizes, shipments will likely be considerably less than 45,000 cars.

Never in the history of the business have the navel oranges been as mature and of as good eating quality at this time of the year as is the case now. The reports from jobbers and consumers alike throughout the East are all favorable to the California navel orange, which has the preference at the present time in practically all markets over any other orange.

The loss in the navel orange crop through splitting is, in our judgment, not considerable in the aggregate, and would not average more than two or three per cent, although some sections report as high as fifteen.

My reply has been based on conditions in all sections, and therefore I can only answer this question in a general way.

Holiday shipments began two weeks earlier than usual in Tulare county and the north, and the quantity going forward before December 10 will be much greater than in any recent year. By December 15 there will be practically no navel oranges left upon the trees in Tulare county and other northern sections.

The quality of the fruit is the very best; in fact, some have felt that it was superior to the fruit of any prior year at the same date. However, fear is expressed that this early ripening and sweetening will mean early deterioration. Already a few puffs have appeared. Cooler weather with rain will probably have a beneficial effect, and if the rain comes we may yet hope to market all the output to the best advantage. Because of the early ripening, and the immense output, the Exchange, and, in fact, all shippers, have been pressing shipments to the limit, and, with fingers on the pulse of the market, the management is crowding forward every car which it is thought the market will take at a fair price. This policy will be continued, and with favorable weather conditions the greatest financial returns California has ever received from citrus fruits will be given.

AIR HELPS PLANT GROWTH.

The value of proper soil preparation to allow aeration in the growing leguminous plants and the forming of the bacterial nodules on the roots is shown in some recent experiments by the department of agriculture.

A light, sandy soil, moderately limed, was used, and the plant selected was the garden pea. Six aerated plants were started in ordinary porous pots and the earth was frequently stirred, corresponding to ordinary garden cultivation. Six nonaerated plants were started in glazed pots with the bottoms plugged with paraffin cotton and the top covered with paraffin paper. After a month's growth the roots of the plants showed eighty-seven nodules on the aerated specimens and only three on the nonaerated ones, while the aerated plants had made double the growth of the others.—American Cultivator.

DEPTH OF CULTIVATION.

It is always well to prepare the ground well before the trees are planted. The earth should be well stirred and free from roots and stumps. During the first years of the life of the young grove the ground may be plowed, if deemed advisable, provided also the plow is not run deep close to the trees. The tree rows should be cultivated comparatively shallow. This treatment will have a tendency to send the roots deeper into the soil as they spread out from the tree. If plowing is resorted to, the depth should be varied from year to year, so that the soil may not become hard and compact at a certain fixed depth, as is likely to be the case if the plow is always run at the same distance from the surface.—Hume's Citrus Fruits and Their Culture.

Deciduous Bush-Tree Fruits

EL DORADO COUNTY STANDARDS.

The following system of standardization is established by the El Dorado County Standardized Fruit Alliance and is practically the same as other counties of the Sacramento valley. In general it was decided to recommend that all fruit destined for interstate shipment from this county be free from worms, scabs, scale or other defect, and, further, that the following specifications be adopted in the packing of the different varieties, respectively, to-wit:

Bartlett Pears.

Must be free from worms, scab, scale and other defects. Wrapped and packed with neatness and uniformity. Of a size not under 2¼ inches in diameter for five tier; or not under 2½ inches in diameter for four tier; and to weigh in either case not less than our former standard.

Six-tier Bartletts will be allowable after the bulk of a grower's crop of Bartletts have been moved; sizes 2 to 2¼ inches in diameter.

Peaches.

To be graded as follows: 90 and larger, 80 and larger and 70 and larger, to the standard box of two layers, for all varieties except Imperials and St. John, which standard shall be 108 and larger.

That three-tier yellow peaches of good color and sound condition of any variety shall be allowable when packed uniformly and of a size not under 1⅞ inches in diameter.

That all packages of peaches shall be marked by the grower as follows, according to the contents, to-wit: "48-70," "70-80," "80-90," "90-108," and "Three-tier," the "90-108" for Imperial and St. John.

That the individual packs shall be practically uniform in size of fruit used and present an even appearance; to be tight lengthwise and sidewise of the box.

Plums and Prunes.

To be free from all disease or defect; to be packed in regular four-basket single crates, three tier to the basket. Of a size not smaller than 5x5, and of approximately uniform size in each tier throughout the crate.

Germans and Splendors shall be allowed solid packed and faced or four-tier.

Two-tier and four-tier plums and prunes of other varieties to be packed under some regulations to be hereafter established.

Grapes.

To be fully matured, carefully picked, and wilted at least 12 hours before packing. To be properly trimmed of all "shot" grapes, mildewed, decayed or injured berries.

That they shall be packed in regular four-basket single crates 4¼ inches in depth, with an eleven-sixteenth cleat under the cover.

That corners of the baskets be properly filled, and the edges of the pack be full and free of straggling berries. That the covers bow slightly, but not over three-eights of an inch.

Cherries.

To be in perfect condition, the right degree of ripeness and color, neatly packed, double faced, with corners of boxes reinforced or well supported so that the box will be full and the surface unbroken, no stems showing at the top or bottom.

Cherries packed all through the box, in even rows, or what is sometimes called four-tier, shall be designated as "Solid Pack."

Other markings to be "8 row," "9 row," "10 row," "11 row," "12 row," as the case may be.

Apples.

A standard pack of apples shall be as follows, to-wit:

That they shall be free from worms, scab, scale and other defects and be approximately uniform in shape in keeping with the variety.

That they shall be wrapped unless otherwise arranged at time of disposal.

That all packs shall be arranged with the stem and blossom ends lengthwise of the box, or diagonal in the so-called half packs.

That all apples not under 2¼ inches and up to 2⅝ inches shall be packed 4½ tiers, the arrangement being 3x2, the same as a peach pack.

That all apples not under 2⅝ and up to 3 inches shall be packed 4 tiers, the arrangement being a square solid pack.

That all apples not under 3 inches shall be packed 3½ tiers, the arrangement being 2x2 the same as peach pack.

This standard does not refer to Lady Apples.

SOIL CONSERVATION.

How to restore and maintain the productivity of the soil is the most important phase of the conservation problem. We are no longer a new nation. We have deluded ourselves with the idea that we have unbounded resources in land, in forests, in mineral wealth. We have been prodigal in the utilization of these resources. We must now pay the penalty of this prodigality. In many of our older communities soil fertility has been reduced below the point of profitable production. Nation-wide effort at the present time, through federal and state agency, is directed toward the restoration of fertility in these localities. On the prairies of the West fertility is beginning to wane. In order that our heritage in the prairie country may not follow the descent of the East and the South, it is necessary that intelligent and vigorous effort be made to farm correctly. We must cease abusing the soil. The renting of land on short leases for the purposes of growing grain for market is one of the surest means of reducing the productive power of the soil. The domestic animal, with well-managed pastures and rational systems of crop rotation, is pre-eminently adapted to the development of permanent systems of profitable farming. Landowners must realize this and must take steps to improve renting methods by stocking farms with a full complement of domestic animals, where the renter is not able to do this for himself, and by giving longer leases, whereby the renter may reap the reward of intelligent management.

The Solution of the Problem.

In the first place, we must increase the number of domestic animals on our farms. Where land is farmed by renters the leases must be made for longer terms, and where the renter has not the capital to provide for the

Planet Jr New No. 76 Pivot-Wheel Riding Cultivator Plow Furrower and Ridger

The greatest one-row cultivator ever invented for cotton or corn. It is a combination of the best features of former cultivating implements, and is really an "all-star" cultivator—without an equal.

Does thorough work, yet is light in draft. It is simple, strong and durable. Made of finest quality materials throughout. **Fully guaranteed.**

proper number of domestic animals these must be supplied by the landowner. We must give more attention to the condition of our pastures. In some parts of this country pastures have been overgrazed until they are nearly worthless. This is especially true in some regions where dairy farming is prominent. Cows are turned on to pastures too early, and the grass is given no chance to make the necessary growth to maintain vitality. Pastures which formerly supported one animal on two acres now support only one on ten acres. This is not universally true, but it is true in large areas. The ranges of the West have been depleted by overpasturing, and in addition are now being settled by farmers, so that the range area is decreasing. There is a serious shortage of livestock in that section, and this shortage must be met by raising more young stock on the farms of the East.

Effect of Live Stock on Soil Fertility.

The effect of live stock on the fertility of the soil needs no demonstration. It is well known to every intelligent farmer. Up to the present time, at least, no system of agriculture has been permanently profitable without the use of domestic animals as a means of maintaining the productiveness of the soil. Whether such systems are possible remains to be seen. It may be that the use of the legumes and other crops producing humus, combined with the judicious use of commercial fertilizers, may serve to maintain high yields, but the supply of commercial fertilizers is not unlimited, and ultimately these soil amendments will have to be dispensed with.

Effect of Legumes.

In addition to increasing the number of domestic animals on American farms, our farmers must pay more attention to leguminous crops and to other crops which provide a supply of humus for the soil. Legumes, such as clover, peas, alfalfa, etc., are especially important because of the fact that with the aid of certain soil bacteria they are able to draw their supply of nitrogen from the air. Having thus an unlimited supply of this valuable plant food constituent, they become very rich in nitrogen. The stubble and roots of a leguminous crop frequently leave in the soil sufficient nitrogen for the needs of the crop that follows. Recent investigations by this department in Kansas and Nebraska show that the average increase in the yield of corn grown after alfalfa, compared with corn grown after nonleguminuous crops, is 70 per cent. A good crop of clover has a similar effect on the yield of crops which follow it. Instances are known where the practice of sowing burr clover in cotton fields in the fall of the year and turning it under in spring in time for another crop of cotton has, in three years, doubled the yield of cotton. Crimson clover sown in a similar manner betwen crops of corn has, in a few years, increased the yield of corn 50 per cent or more.

The reason these leguminous crops have such a marked effect on fertility in many case on depleted soils, lies in the fact that nitrogen is not a constituent of the soil proper, but only of the decaying plant and animal matter in the soil. When soils are farmed for many years without any attention to their fertility, this organic matter is rotted out and the nitrogen disappears. Hence nitrogen is nearly always the first plant-food constituent to become deficient in the soil.

The fact has already been referred to that we export a large proportion of our cottonseed meal, oil meal and other rich nitrogenous feeding stuffs. In 1908 we exported linseed-oil meal to the amount of 696 million pounds, cottonseed meal 929 million pounds, and corn-oil cake 66 million pounds. These materials are all exceedingly rich in nitrogen. They should be kept at home, fed to live stock and the manure returned to the land.—W. J. Spillman in Farmers' Bulletin 406.

NO SURPLUS OF GOOD FRUIT.

It is an interesting fact that the great extension of fruit growing, in all parts of the country, has been attended, not by a decline in prices but by a very considerable advance. The question whether or not the multiplication of orchards and berry patches will have the effect of producing a glut, so as to render profitless the labor and expenditures of the fruit grower, seems, then, very likely to meet a negative reply.

In the first place the demand for all the fruits of North America is world-wide. The world's appetite for them is insatiable; and as the facilities for distributing them are better systematized through intelligent cooperative arrangements between growers and transportation agencies, and selling agencies in the cities, it seems as though the problem is to be, not how to get rid of surpluses, but how to get enough of any kind of good fruit.

In years of great abundance in American apple orchards, good apples have sold in Mexico at 15 cents apiece. In London they have retailed at 25 cents apiece. Other fruits, capable of bearing transportation for long distances, have commanded proportionately high prices. Of course, these prices have been for choice fruit. In New York and Boston even 10 and 15 cents apiece has been readily obtainable for choice apples.

Such exceptional figures as those above quoted are not, however, necessary as a basis for profitable fruit growing. The moderate prices paid by the mass of American consumers are sufficiently high for that; as in thousands of houses our people are learning to prefer fruit, at such moderate prices, to many another article of food which they have heretofore demanded.

The improvement of canning processes and the cheapening of apparatus has also its effect in insuring a market for fruits. Fruit farmers are not now depending on "canneries." Recent inventions enable them to do the canning themselves.

It would seem, then, that the grower need only see to it that his fruit is of good quality, attractively put up and intelligently marketed to be certain of a reasonable reward. But the day when neglected orchards and bushes could be depended on to produce salable crops has passed. The grower of today must be equipped by study for battling with insect pests; must be insistent in cultivation and in the use of the sprayer and must, in short, give as close attention to his trees as the stockman does to his cattle, the doctor to his patients, or the merchant to keeping his stock of goods fresh and in salable condition. —Market Grower.

Irrigators near Hemet and San Jacinto, Riverside county, are intensely interested over reports of a big dam and power plant in the San Jacinto mountains, for which the government has already granted a franchise.

Home Grounds Beautiful

THIS MONTH.

Hardy annual seeds may be planted this month and even late planting of sweet peas is in order. Peas already up need attention and if this dry weather continues heavy irrigation to fill the subsoil will be necessary. The long drouth makes a condition of soil hard to handle. Long continued irrigation is required. A bit of high-grade sulphur scattered about the pea vines will aid in preventing mildew.

Gladiolus may be planted for early spring blooming.

Lawn making is in order. In fact, it's an excellent time to start a lawn. Bermuda is slow to start at this season of the year, so blue grass and white clover get well established before it manifests itself.

The old lawn should be given a good dressing of well-rotted stable manure or if preferred, commercial fertilizer.

Prune all deciduous shrubs and shade trees before the sap starts, also set deciduous plants at this time.

A heavy dressing of stable manure on beds for later planting may be spaded in and irrigated. It is the best of preparation for the soil.

SHRUBS AND VINES.

Whether a shrub exists as a specimen or is forming a part of some useful foliage mass, its chief charm lies in the grace and beauty of its form. It is the flowing line of its natural contour that delights us. So this characteristic of untrammeled nature should be our careful guide in all that pertains to pruning. All the accruing benefits of pruning are never sufficient to warrant any considerable sacrifice of the graces in the line of natural growth. If these are to be violated through ignorance of what is right or through careless workmanship, it is much better to refrain from pruning, and, whenever there is any doubt as to what it is best to do or as to whether the laborer is sufficiently skilled, it is well to forego the attempt. For when once the harm is done the loss is usually irreparable. On the other hand the benefits derived from pruning are often very slight, and never are they comparable to the advantages enjoyed by the fruit trees and bush fruits. In the ornamental we do not desire primarily unusual vigor of plant nor extra size of fruit, but the normal, healthy development of all the various features. The failure to distinguish between the functions of the fruits and the functions of the ornamental shrubs has led to a general demand for pruning, an indiscriminate practice of it, and a great loss in real beauty.

BEAUTIFY THE HOME.

The home is the resting place, the place where we are supposed to spend our leisure hours and enjoy the fruits of our labors; consequently the house should be comfortable, sanitary and attractive. The surroundings should also have constant care; the lawn, flower beds, walks and shrubbery should have regular attention. There are none of us but have some time to spare for the enjoyment of a lovely home. Why should we live our lives out and spend our days in a "ram-shackle" old house, surrounded by an unkept yard and broken-down fences? Some say that they will do so when they get a little money ahead. Well, that may never happen, and when it does this money usually goes for something else and the home remains unattractive and neglected. It does not require much money to make your home attractive, and if more of the men would take an interest in this beautifying and cleaning up they would find that a goodly amount of pleasure can be gotten out of it and that the money used is not only well spent, but would not be missed. In fact, if everything is kept in repair and attention given to things when needed, it would be a saving of money instead of an expenditure. Neat and well-kept premises are an indication of thrift and every farmer should have pride enough about him to make his home the most attractive and well-kept one in his neighborhood or his county.

SOME NEW GLADIOLI.

At a recent meeting of the Royal Horticultural society in London, the public was astonished to see a magnificent display of hybrid gladioli from Germany. The exhibitor, Wilhelm Pfitzer, of 74 Militar Strasse, Stuttgart, simply took the place by storm. The collection was remarkable not only for the size of the individual blossoms, but also for the vigor and freedom of the upright spikes. The variation in color was also remarkable, and nearly all shades except blue were to be seen. English gladioli growers are content to stick to a few colors. Not so Wilhelm Pfitzer. He has mixed the gandavensis, branchleyensis nanceianus and Lemoinei hybrids up so beautifully that it has now become almost impossible to distinguish "t'other from which" in the progeny. Botanists will simply tear their hair in despair if gardeners are going to continue to cross hybridize plants in greater quantity in the future than they have in the past.—Gardening.

The China asters are amongst the best of all the annual garden flowers. They are of the easiest culture, most free of bloom, and comprise a multitude of forms and colors. They are therefore admirably adapted to profuse and generous effects in schemes of planting. They are also worthy of wide attention because they are adapted to many of the purposes for which chrysanthemums are grown, and they can be raised to perfection wholly without the use of glass. They attain their best in the decline of the season, from late August till frost, at a time when many of the annuals and the greater part of the perennials are spent and gone. No garden flowers carry such a profusion of bloom and color down to the very closing in of winter. The aster border still had blooms when the snows fell in November, and when even the wild golden-rods had waned and died.

Keep potted plants well watered. Many persons will pour a little water on a plant, enough to soak in an inch or two, and wonder that the plants do not grow. The trouble is that the growing part of the plant receives no nourishment. Plants should be watered every day, and in such a way that the roots get plenty of moisture. The soil should be rich.

TREES

Ornamental

Our almost endless variety of stock for ornamenting small gardens, extensive grounds and parks; for street planting and interior decoration, will appeal to every plant lover. Space will not permit us to more than briefly mention a few varieties in this column.

Roses

Beautiful, strong field grown plants; varieties adapted for hedges, grouping, climbers, etc. Known varieties of merit both in bush and tree forms.

Shade Trees

Acacias, Camphors, Pepper Trees, Grevilleas, Magnolias, Pines.

Decorative Shrubs

Altheas, Duetzias, Ligustrum, Lilacs, Spireas, Eunoymus, Oleanders, and many other beautiful plants.

Eucalyptus

The ornamental value of the Eucalyptus is considerable in addition to its recognized merits for practical purposes. We have a good stock on hand, including many varieties.

Palms

California Fan, Phoenix Canariensis, Erytheas, Cycas, Kentias, Rhapis. Also all varieties of house palms.

Climbing and Trailing Plants

We also call attention to our large selection of climbing and trailing plants such as **Ampelopsis, Ivy** and **Honeysuckle**; also Border Plants and Bulbous Roots.

LET US HELP YOU PLAN YOUR GROUNDS

We have secured the services of an expert landscape gardener and are prepared to furnish plans and give advice as to the most suitable trees, plants and shrubs to use in ornamenting your grounds at reasonable cost.

WE INVITE CORRESPONDENCE

from any persons desiring information about varieties to plant. Our book entitled, "California Horticulture" is of great assistance to all fruit growers, not only containing detailed description but instructions for planting, care of stock, pruning, etc. The price is 25c, but to all persons who will send us a probable list of their wants for prices we will send this book **FREE**; also our NEW ILLUSTRATED PRICE CATALOG—something novel. Be sure to mention this ad when writing.

Garden and Field Crops

THIS MONTH.

Plant almost everything of the hardier nature—cabbage, carrots, cauliflower, beets, lettuce, parsnips, radishes, salsify, etc. Reset rhubarb, horseradish, asparagus. In the most sheltered places, where frost is practically unknown, plant potatoes. Tomatoes, peppers, cucumbers and egg plant may be sown in hot beds for planting in favored locations later.

Clear all rubbish from garden, and burn or compost for use in orchard or on alfalfa later. Clean, well-rotted manure may profitably be scattered and plowed or spaded under. If well rotted, no danger need be anticipated from weed seed. Commercial fertilizer is good, but not to be compared to stable manure for the garden. A supply of nitrate of soda on hand to stimulate quick growing plants is desirable, because the cold soil may be deficient in available nitrogen.

Plant strawberries and all other small fruits this month.

Don't wait for a big garden, but, if only a rod square, grow something for the table. It's worth the effort, and a square rod will yield wonderfully under intensive culture.

THE STORAGE OF SWEET POTATOES.

The keeping of sweet potatoes in storage is one of the most important problems the grower has to deal with. All the growers know that if the crop can be successfully kept until the holiday season or a little later, a much more remunerative price can be secured for the potatoes. It is the purpose of this bulletin to give some of the methods of storage in use today on the farm. There are a few things that should be kept in mind when handling the crop and when storing:

1st.—Dig the potatoes carefully and dry thoroughly in the sun.

2nd.—Sort out the sound ones and handle them carefully; for a bruised potato does not keep well.

3rd.—Keep the potatoes from getting chilled.

4th.—Place the potatoes where they will be dry and warm. A temperature of from 50 to 65 degrees has been found to be about right for keeping sweet potatoes.

Storing in banks. Make a circular bed about six feet in diameter, in some sheltered location, by throwing up the dirt from the sides. Put on top of this a few inches of straw or hay. Place on end in the center of this ventilator flue about six inches square and four to five feet long. The flue should be bored full of holes up and down the side, to afford abundant ventilation. The potatoes are then piled around the flue in a conical heap. The amount of potatoes to put in each bank is from 1000 to 2000 pounds. The tubers are then covered with hay or straw or other material to a depth of three or four inches. On top of this is put two or three inches of dirt, and this amount should be increased as the weather grows colder. The heap should not be covered too deep with dirt at first, as the potatoes most always go through a sweat and loss is likely to occur if covered too deeply. The heap ought to be examined in a week or ten days after putting up, and if too much moisture is present, uncover the pile and let dry as they stand for a few hours, and then cover again.

Storing in sand. The tubers may be taken to a dry warm room and then stored in sand. A tight room in an adobe building will answer the purposes well, if some ventilation is provided for. The method of procedure is as follows: put on the floor a layer of sand two or three inches deep, and on this place the potatoes side by side until the sand is covered. Then pour dry sand over them until covered, and then place on more potatoes and cover as before. A good many layers may thus be put on top of each other, until several feet in height has been reached. When doing this it may be necessary to place some boards on the sides and in front to keep the sand in place. This method of storage has been used at the Station with very satisfactory results. A number of the Mexican farmers use this method every year to keep their potatoes. From information obtained it has been a very successful method with them.

Storing in straw. Storing sweet potatoes in straw or hay offers a very easy means to the consumer and grower of keeping a small amount for home use. In a warm room or stable, place the potatoes in thick layers of straw, where they will not be disturbed or tramped upon by those entering the room or barn. As the weather grows colder the thickness of the straw should be increased.

When storing sweet potatoes it will be found profitable to pay close attention to details. The potatoes should be kept dry and warm, and be properly ventilated.—J. E. Mundell, New Mexico, Col. of Agr.

SELECTING SEED POTATOES.

A good deal has been said about getting proper potato seed, as well as seed of other field plants. Most growers are generally well up to date on the growing of grains and breeding of stock. There is more than one phase in the growing of seed potatoes in the North, and if the average potato grower would only take a little trouble in selecting his seed from his own stock, instead of letting it run out by a careless or a haphazard way he never would be obliged to pay outrageous prices for seed potatoes.

A potato is different from an ear of corn or an onion, as the individual is not the whole family as far as the seed proposition goes, but an individual potato is only one out of a setting and when it is the only desirable one in the hill you can rest assured it is a full brother to all the little ones in the same hill. The idea is to see the entire setting in a hill of potatoes. If there are six to ten good-sized ones and the balance of them fair-size they are the ones for seed, and by following up this proposition of selecting by family instead of individuals every year growers will never be in want of good seed of their own growing. The same principle applies to tomatoes or any other similar plant that grows a family of fruit perennially.—New York Packer.

Live Stock and Dairy

Dairymen and stockmen are requested to write of their experience. Mrs. Sherman is always willing to answer queries and this, with experience of other workers, will make this department of greater value.

WHOSE LOSS?

By Mrs. M. E. Sherman.

The question in regard to who should stand the financial loss when cows are condemned under the tuberculin test is assuming great prominence in the minds of dairymen. The ordinances of many towns require the cows to be tested before the dairy is given a permit to sell milk in the town. Some men have tested their herds and continued their business, while others have legally tested the ordinance and found it was faulty. The natural feeling of the dairymen is that if the cows react, the condemned ones should be paid for by the authorities ordering the test, or by the state. This question is discussed in a heated manner, and much ill feeling is manifested against those who do not agree that the cows should be paid for by anyone but the owner.

Protection.

Until matters are better regulated, the man with a tested herd has to meet the careless ways of his neighborhood. The man on the adjoining farm, so long as he feeds the diseased cows' milk only to his own family, cannot be forced to destroy the animal. These cows may be staked along the fence lines, or even break through the fences and mingle with the herd that has been carefully tested. The dairyman that has a clean herd has no protection against this occurrence. These straying animals may appear, and one may be diseased, and, coming into contact with healthy cows, start the trouble again.

Reforms.

Every reform has its martyrs, and the dairyman today feels that he is one of them. The fact is, the man with a healthy herd has no encouragement, except in the commercial saving of further loss of cows, to make the tests. At the present time the man who regularly tests his herd is viewed with suspicion, as one having the disease, rather than as one maintaining a clean herd. One man put the usual view of the case when he said: "If you have not the disease, why do you wish to test?" It seems hard to make it understood that one diseased cow in the herd is constantly infecting the others. It is also hard to make it understood that a cow may look, eat and seem well, and yet have the disease. When the cow becomes seriously ill with tuberculosis, anyone can discover it, and at the same time she is worthless as a milker.

Recompense.

The cows that do not show any troubles to physical examination, and yet react to the tuberculin test, should be paid for, I think, if any class of payments for business losses can be construed as proper to be met by the public funds. The plea is made for the poor man whose whole possessions are his cows, and when to destroy them is to confiscate his living. Yet many dairymen have lost their herds slowly by tuberculosis and by contagious abortion, while others have met their Waterloos in Texas fever. Nothing has ever been thought about helping them, even if they were poor men. I could an equally tragic tale unfold of the losses of raisin growers after they had done all their work and made a good and perfect raisin, only to find the market destroyed. Phylloxera and California vine disease have ravaged many a vineyard, yet the state has not been asked to help the owners. These people were as innocent as the dairymen in doing anything to make them responsible for these terrible losses. Then take the cases of the colony schemes that have placed new arrivals on land impossible of successful cultivation. In one case the land was not even owned by the man selling it. When his option expired, the land reverted to the former owner, with all the colonists' improvements. Another case was where people were settled to grow fruit on land that had a frost every month in the year. It was only said that people must be more shrewd. The dairyman that is wise must be shrewd enough to test his herd every six months, and keep the trouble out of the herd.

In the present high prices of wheat, have we forgotten the losses of the wheat men? Only a few years ago, I had a good neighbor, a man of helpful spirit, kindly in every way, yet he went under in the losses of a few crops. His mule teams were the county's pride; the thousand big sleek fellows that trailed the gang plows and moved the harvesters over the forty thousand acres of level valley land, all were lost. Prices were bad, and dry years came, notes fell due, and land and mules were swallowed up. The wheat was wholesome and not condemned as food, yet poverty came to the owner, and the state gave him no redress. The loss by tuberculosis in the dairy herd must be considered in fairness as a loss incident to the business, and the cleaning up may well be enforced by the state as a protection to the innocent consumers. The prices of milk and butter may be higher when the cows are destroyed, and the remaining product bring in as much money as now received. So, while cows are scarcer, the net profits may not be as much reduced as the dairyman now fears.

In a moral sense, the dairyman has a rare chance to show an enlightened public spirit that will make him clean his herd from tuberculosis, no matter what the personal cost. Affection keeps one from correct judgment at times, and the loss of a cow is often more than her money value, for to one that loves them, the personal matter comes in like losing an old friend. On the other hand, if the expense were saddled on the state for all the cows condemned, it would not be greatly felt by the taxpayers, as the proportion each would pay would not be very great. The testing and removing of diseased cows is certain to come within a short time. The babies must be protected against diseased milk. If all the milk used cannot be had from cows that have passed the tuberculin test, then, at least, the poor man should receive a bounty that will pay for certified milk for the baby in his family.—M. E. Sherman.

HISTORY AND PECULIARITIES OF THE MULE-FOOT HOG.

W. J. Spillman, U. S. Dept. of Agriculture in American Breeders' Magazine.

The principal peculiarity of this breed lies in the fact that the hoof is solid, like that of the horse or the mule, instead of being cloven, as in ordinary swine. In other characteristics they do not differ noticeably from common breeds. In color they run the whole gamut of swine colors, though most breeders are endeavoring to establish solid black as a breed characteristic.

Distribution in the United States.

The idea is prevalent in this country that these hogs originated in Arkansas and the Indian Territory, or what is now the State of Oklahoma; but from what follows it will be seen that this is doubtful, though they have been common in that section for more than half a century. Mr. C. E. Quinn, who was formerly connected with the Department of Agriculture and who was interested in this breed of hogs, secured addresses of breeders of mule-foots as follows: Indiana, 145; Missouri, 16; Illinois, 13; Iowa, 12; Ohio, 9; Minnesota, 8; Arkansas, South Dakota and Wisconsin, each 4; Kansas, Kentucky, Nebraska and South Carolina, 3 each; California and Texas, 2 each; and 1 in each of the states Alabama, Georgia, Louisiana, North Carolina, Oklahoma, Pennsylvania and Tennessee; a total of 235 breedrs in twenty-two states. This shows that the breed is rather widely distributed. Two breeding associations have been formed for the registration of mule-foots, one at Mammoth Springs, Ark., organized in 1904, D. D. Gilson, president; the other organized in 1908 at Indianapolis, Ind., W. H. Morris, secretary.

History.

In the short time I have had to prepare this paper I have been unable to verify the statements which follow concerning the history of these hogs. One breeder in the state of Oklahoma says: "These hogs some sixty years ago were originally brought from the South Sea Islands and turned loose in the Kimish and Little River Mountains in the Choctaw Nation for the use of the Indians, and have lived there up to the present time." He further states that he has a considerable trade in these hogs with zoological parks. He does not give his authority for the statement concerning the shipment from the South Sea Islands.

Other breeders in their catalogues, make the claim that the mule-foots originated from a cross between the peccary and the hog. This claim is evidently based upon the supposition that the peccary has a solid hoof, which, however, is not the case. The peccary does lack one toe on the hind foot, but it is one of the small hanging toes, so that the peccary has a split foot like that of the ordinary hog.

Another breeder states that the mule-foots were brought to Delaware from Sweden in the year 1637. This statement is of some interest in connection with a statement of Mr. Q. I. Simpson, of Palmer, Ill., that an old writer speaks of a solid-hoofed breed in Sweden in the vicinity of Udall. Mr. Simpson is also authority for the statement that one of his neighbors, Mr. Madison Curvey, on a trip to Texas some sixty years ago, saw these hogs in the Choctaw Nation, and states that the tradition of peccary ancestry was then held by the squaw men. Mr. Simpson further states that Darwin, in 1859, mentioned the appearance of these hogs in Scotland. Mr. Madison Curvey, above referred to, also states that he saw mule-foot hogs at Nauvoo, Ill., in 1844. Mr. Simpson further states that Aristotle, in writings entitled "Researches about Animals," about 370 B. C., tells of solid-hoofed swine in Greece.

While I have not had an opportunity to verify the evidence here presented, it suggests that solid-hoofed hogs have come down from ancient times, and it is not improbable that this characteristic has been found in certain strains of hogs since these animals were first domesticated.

Relation to Cholera.

Not the least important fact concerning this breed is that breeders are selling mule-foot hogs with the guarantee that they are immune to cholera. The writer has seen numerous statements from farmers who claim that they have exposed mlue-foot hogs to cholera and that none of the hogs took the disease. He has seen one or two statements from farmers contradicting this. Recent tests at some of the experiment stations indicate that the claim of immunity to cholera is not well founded. Mule-foots exposed to cholera died as promptly as other breeds. The Indiana State Experiment Station has made such a test, and reports as follows in Bulletin No. 140 (1910):

Four pure-bred mule-foot hogs and four hogs of mixed breeding, averaging about 40 pounds in weight, were used in making the test. The hogs were exposed in the natural way, by turning them into an infected pen in which hogs having acute hog cholera had died. All of the mule-foot hogs contracted the disease, three developing the acute, and one the chronic form. Three became fatally ill and the fourth recovered after several weeks. Three of the hogs of mixed breeding sickened and died or were killed, and the fourth showed no symptoms of disease.

It is interesting to note that in crosses between mule-foot hogs and ordinary breeds the mule-foot character seems to be dominant. Some hogs of mixed breeding have hoofs that are solid at birth but in wnich the toes split apart usually at about nine months of age. In some individuals the rear toes split apart in this manner, while the front toes remain solid through life. An anatomical study of a series of bones of these mixed breed hogs would probably reveal facts of considerable interest in connection with the inheritance of the mule-foot character.

FEEDS AND FEEDING.

"Feeds and Feeding," a hand-book for the student and stockman, is just issued in the tenth edition, and has been revised and entirely rewritten by W. A. Henry, emeritus professor of agriculture, formerly dean of the College of Agriculture and director of the Agricultural Experiment Station, University of Wisconsin.

The new "Feeds and Feeding," a well-printed volume of 613 large pages, is practically a cyclopedia of animal nutrition and the rational feeding of farm animals, told in simple, helpful language. The information has been gleaned from hundreds of thousands of pages of technical jour-

The Best Separator Today

is the

U. S. Cream Separator

You do not care who invented the Cream Separator. You want to know which is the **best separator today.**

The **United States Separator** has demonstrated its absolute and complete superiority over all other Separators. It holds the **world's record** for closest skimming, in fifty consecutive tests, continuing through a period of thirty days, with the milk of ten different breeds of cows. It was awarded the only **Grand Prize** at Seattle, 1909.

Cream skimmed by the **United States Separator** is used by 99 99/100 per cent. of all creameries. They can't get enough U. S. Cream. We originated and perfected the cream gathering system which has put whole milk factory separation out of business. Not 10 per cent. of the **whole milk factories**—of which a "would-be-competitor" claims a monopoly—that were in operation 10 years ago, are running today.

Closest skimming, easiest running, easiest to wash, longest lived—these are the chief reasons why the U. S. is the best separator of **today.** Don't buy any separators until you have sent for catalag No. 20.

nals, scientific reports and bulletins of old and new world experiment stations. These original sources of such information are largely inaccessible to most persons who need the information.

Part I, 128 pages, shows how plants grow and elaborate food for animals, and how farm animals live and grow on the food they consume.

Part II, 122 pages, sets forth the nutritive properties of practically all American feeding stuffs, and how these can best be utilied in feeding farm animals.

Part III, 302 pages, summarizes practically all the typical feeding experiments with farm animals. The data, expressed in the fewest possible figures, and tersely discussed, report the exact amount of food consumed by one farm animal—the horse, calf, steer, cow, sheep and pig—in one day, and the returns therefor in work, flesh, milk, etc.

The Appendix, covering 29 pages of figures, shows the composition and digestibility and fertilizing value of practically all the new and old world feeding stuffs.

The 20-page, double-column index of over 3,000 references enables the reader to surely and quickly find every statement.

"Feeds and Feeding" is not only a book for the student, but also for the busy farmer and stock man, who can take it up at any time, open at any place, and there find interesting, helpful, up-to-date information on the rational feeding of farm animals.

The book can be secured through The Cultivator or of the author. Every stockman should own it. Send The Cultivator $2.25, and the book will be mailed postpaid.

CROSS BREEDING OF SWINE.

Many farmers have discovered by experience that the crossing of breeds of swine usually results in more vigorous stock. Just why this is, it is not easy to understand. The only reasonable theory that we have been able to formulate is that by cross breeding you entirely avoid close line breeding.

Cream Separators, all sizes and prices. O. J. Weber Co., 225-227-229-231 East Sixth street, Los Angeles.

It is very difficult to secure well-bred sires of any of the popular families without very close line breeding. The farmer may not know it, may not in fact even suspect it, and can not by any means discover it unless he goes to the trouble of securing an extended pedigree of the sire that he expects to purchase. In any of the fashionable strains he will usually find that it runs back quite a number of times to the same noted sire that gave the strain its reputation. Hence cross breeding avoids line breeding; and it has always seemed to us that this was the main reason for the acknowledged superior vitality of cross-bred hogs.

The farmer, seeing such good results, concludes that he has developed a new breed, and proceeds to use them as breeders. Then he discovers his mistake. The first cross may be superb, but in the next cross he will naturally discover the traits of all the different ancestors that gave character to the sire he has used. This is what is meant by atavism, or harking back to remote ancestors; and if he wishes to see the full development of atavism, let him use one of these cross-breeds on the rest of the herd, thus insuring more or less of the same blood and giving every opportunity to throw back.

There is great advantage in crossing, in that we can often secure superior milking qualities in the dams and superiority of form in the sires. For example, breeding a Berkshire on Poland China sows will secure the (usually) better milking qualities of the Berkshire, and thus insure well-nourished pigs, and secure at the same time the fine fattening qualities of the Poland China. It is therefore frequently desirable to cross breed, but never unless you intend to put the whole progeny in the fattening pen. Any other course of action would be ruinous.

The general rule is to keep the breeds entirely separate, using always pure-bred sires, whatever the dams may be. The exception is when you have brood sows enough for another year, in which case you can safely cross breed, if you like.—Wallace's Farmer.

HOW MUCH MANURE WILL A COW PRODUCE.

The experiments at the New Jersey Experiment Station showed that each cow voided in manure and urine seventy pounds a day. The production for the year then would be twelve and three-quarter tons. The urine is worth more than the solid manure. It has been estimated that the urine of a 1000-pound cow was worth $13 a year and that of a horse $18 a year. How correct this is we cannot say.

But there is certainly enough of value in it to induce the farmer to save it all. There is less loss in all of the elements of manure if it is hauled upon the land as soon as made ever day than if allowed to stand in heaps. But if it must accumulate in heaps as is the case in summer time, it is a good thing to sprinkle a few pounds of land plaster on it each day to absorb and hold the ammonia until the soil can get it.

The more a farmer studies this proposition of keeping up the fertility of his land, the more important does the preservation and measures he takes to preserve the manure become. This means true economy. Passing a farm the other day we saw a farmer hauling out manure that had lain in the barnyard a year. It had lost fully half of its original value. But that was not all of the foolish things he was doing. He was dropping it in heaps on the land instead of spreading at once as fast as hauled, when the work could be done at the least expense of labor. Very likely those heaps will remain unspread for a month or two. We have seen them remain till spring. Now, had that farmer a clear sense of economy of labor and the right idea of getting the full value of his manure? We think not.

It is these wastes and there are many of them, that call for constant preaching, constant effort to make men read, think and understand their work.—Hoards Dairyman.

Jersey cows get their name from the Island of Jersey, where they have been brought up to a high state of perfection. They make the best of family cows on account of their great butter yield.

Warranted to Give Satisfaction.
Gombault's
Caustic Balsam

Has Imitators But No Competitors.
A Safe, Speedy and Positive Cure for Curb, Splint, Sweeny, Capped Hock, Strained Tendons, Founder, Wind Puffs, and all lameness from Spavin, Ringbone and other bony tumors. Cures all skin diseases or Parasites, Thrush, Diphtheria. Removes all Bunches from Horses or Cattle.
As a Human Remedy for Rheumatism, Sprains, Sore Throat, etc., it is invaluable. Every bottle of Caustic Balsam sold is Warranted to give satisfaction. Price $1.50 per bottle. Sold by druggists, or sent by express, charges paid, with full directions for its use. Send for descriptive circulars, testimonials, etc. Address

CONTENTS THIS WEEK

SQUIRRELS CAUSE DEATH, 3.

CITRUS AND TROPICAL FRUITS.—Use of Potash; Drink Juice; Wars of Insects; Guava; Whitefly Investigation; Record Breaking Output; Air Helps Plant Growth; Depth of Cultivation: 4, 5, 6.

DECIDUOUS BUSH-TREE FRUITS.—El Dorado County Standards; Soil Conservation; No Surplus of Good Fruit: 7, 8.

HOME GROUNDS BEAUTIFUL.—This Month; Shrubs and Vines; Beautify the Home; New Gladioli: 9.

GARDEN AND FIELD CROPS.—This Month; Storage of Sweet Potatoes; Selecting Seed Potatoes: 10.

LIVE STOCK AND DAIRY.—Whose Loss; Mule-Foot Hog; Cross Breeding of Swine; How Much Manure Will Cow Produce: 11, 12, 13.

EDITORIAL.—A Valuable Publication; Responsible Nurserymen; Fire Day; Rain; Southern California Poultry Breeders' Association: 14.

AGRICULTURAL NEWS NOTES OF THE PACIFIC COAST.—Northern, Central, Southern, The Coast: 15.

PRACTICAL POULTRY CULTURE.—The Houdan; Profit in Broilers; Doctoring Sick Fowls; Sunflower Seed; Ducks; Correcting Defects; Increase the Profits; Advertising Suggestions: 16, 17, 18.

IRRIGATION AND FORESTRY.—Work of Government in Forest Products: 19, 20.

QUESTIONS AND ANSWERS.—Balanced Ration for Cow; Canning Peaches; Fencing Against Gosphers; Book on Goats; Squab Turkeys; Age of Ducks; Water Power; White Holland Turkeys; Salt Bush; Sore Mouth; Alfalfa Tea for Calves; Alligator Pears; Sycamores; Influence of Bud; Fertilizer for Berries; Substitute for Milk; Dynamometer; Bermuda; Red Scale; Blastophaga; Pushing Buds Up; Spray for Lemons: 21, 22, 23.

VETERINARY.—Tuberculin Test; Cough; Chronic Scours; Warbles; Blind Teeth: 23.

TIMELY RANCH SUGGESTIONS.—System of Soil Culture: 24, 25.

ENTOMOLOGY AND BEES.—Legislation: 27.

GENERAL HOUSEHOLD NOTES.—The Man Who Wins; When Gordon Acted on Impulse; Texture and Flavor of Meat: 28, 29.

PRODUCE MARKET.—Los Angeles Market, San Francisco Market; Deciduous Market; Citrus Market: 30, 31.

A VALUABLE PUBLICATION.

The Pomona College Journal of Entomology, now in its second year, has been largely devoted to the more scientific discussion of entomological questions. In the December number it takes up the more practical or economical side of entomology. It has a long discussion by Horticultural Commissioner Essig of Ventura county on the citrus mealy bug and its distribution in California. Engravings show its work on the tree and the fruit of the lemon. Mr. Crawford discusses the Mexican orange maggot; Mr. Coolidge, the California orange dog. Other scientific considerations of entomological subjects are given by Messrs. Distant, Crawford, Chamberlin and Grinnell.

The Journal is edited by Prof. C. F. Baker of Pomona College, the work of getting it up and contributions are gratuitous, and the cost of production is borne by several orange growers of Southern California. It is hardly probable that such a magazine will ever be self-supporting, but growers should give it all the encouragement possible.

RESPONSIBLE NURSERYMEN.

Eastern horticultural papers are warning against nurserymen who contract to sell and plant fruit trees, maintaining them for a period for a consideration. It is possible some such nurserymen are responsible; it is more probable that many of them are irresponsible, at least if we may judge from the past years. From Denver and the Northwest especially has come complaint of swindling operations of these nurserymen. An agent appears and contracts, for instance, to set out seventy apple trees per acre and care for and prune and replace all trees dying within a period of three years, for $35 per acre, or 50 cents per tree. One grower reports that he signed such a contract, and that his trees were planted, but a great number of them died. He complained to the company by mail, but his loss has not been made good. Meantime a "settlement" has been effected with him, by which he paid far more in cash than good, thrifty trees could have been purchased and planted for.

The best way is to deal with responsible nurserymen of our own state.

FIRE DAY.

California may be burdened with legal holidays, but we note the observance of one in Nebraska which we believe would be a valuable addition. It is called "Fire Day," and is observed by the public schools of the state. Its observance has been brought about by the suggestion of the state fire warden, and the object is to make the day one of instruction on fire prevention and extinguishing. Pamphlets of instruction are issued, and it is urged that parents supplement the work of the schools by emphasizing the lessons of the day. This effort is more particularly in the interests of the thickly populated sections, where fire is a great menace. Judging from the statistics of fire losses in the United States, such a movement is dictated by wisdom. The annual losses from this cause the country over aggregate $250,000,000. This is a loss of over $2.50 for every man, woman and child in the United States. The average annual fire loss in continental Europe is only 33 cents per capita. The great loss in this country compared with that in Europe is no doubt due in part to our lighter construction of buildings. European cities are more generally built of stone and cement. This condition will to a certain extent be corrected as our country grows and fireproof buildings are constructed, but these lessons should be impressed upon our young people.

In California, and, in fact, in all the arid West, a still greater lesson of fire loss may be taught with regard to our watersheds and lumber interests. The losses of the past year have mounted to such magnitude that closest attention must be given to prevention of similar occurrences. The Superintendent of Public Instruction of California has shown himself alive to topics of the day. We suggest for his consideration, and that of other educators, a fire day in this state, in which the duties of campers, hunters, careless smokers and others who enter the forests may be made emphatic.

RAIN.

We hope before these words are read that a little rain at least may have been given to the state, but up to this time the promise of an exceedingly dry season seems to be all that we have. Moralizing or even complaining does not help the situation in any way, or even reference to past years' totals to show that other seasons have been similar, is but little comfort. It is a common saying that no two summers are different and no two winters alike in California, so that precedent has no assurance for us. But we know there is nothing gained by the complaining spirit. The only gain is through conservation of every drop of water by the use of enlightened methods of winter irrigation. Saving of moisture through cultivation is also a factor, but we hope the "change of the moon" which is promised to bring us rain a week or two later will make good.

SOUTHERN CALIFORNIA POULTRY BREEDERS ASSOCIATION.

The Southern California Poultry Breeders Association gives its sixth annual exhibition at Luna Park, Los Angeles, January 5-11. The San Diego Show also begins this week, so that Southern California fanciers are offered opportunity to see some exceptionally fine birds.

The Florida Fruit Exchange has been so successful with citrus fruits during its first year that one of the sub-exchanges has notified its members that it will handle, in addition to citrus fruits, tomatoes and celery. This is announced that other sub-exchanges may fit themselves to handle garden truck, so that the big organization promises to benefit the market conditions of Florida along all lines. We hope this will be successful, for one big organization handling this produce will be more satisfactory than many smaller ones. But the California Exchange has been so successful, and has stuck so closely to its one line of citrus fruits, that we cannot help but wish that the Florida Exchange would perfect itself along one line before branching out. We wish it all kinds of success, however.

The specialization movement has again been shown in Colorado, where a call has been issued for a convention to meet at Greeley, January 6th. This call was issued by the Weld County Farmers' Club to all farmers and commercial organizations in Colorado to attend a "State Convention for considering ways and means to remove the grasshoppers as a factor working against Colorado's prosperity." In that state the grasshoppers are spreading with the increased growing of alfalfa, and it is feared their ravages may become permanent unless methods of general control are adopted.

As an illustration of how the by-products of a manufacturing process may become of great importance it is announced in the Kansas Farmer that the ginners of the Texas cotton fields are advertising to gin the farmers' cotton free and pay them a bonus of from $7 to $8 per bale in addition provided they are allowed to keep the seed. It has not been long since these same ginners were charging for their work of ginning the cotton and were keeping the seed as well. The seed is now worth practically as much as the fiber.

Several states are considering the advisability of giving compensation to the owners of animals destroyed to prevent spread of contagious diseases. At the present animals which are liable to spread germs of tuberculosis may be ordered destroyed by state authorities, and the entire loss falls upon the owner. This is certainly most unjust and almost disastrous. For the well-to-do stock owner who has large numbers of animals which may be infected with the same disease it is possible the benefit may more than make up for the loss, but as a rule the action of the authorities is for the general good, and, such being the case, it seems only fair that the entire state should bear the loss, instead of forcing it upon the unfortunate owner of the infected animal. Municipalities are taking steps in this matter, and are insisting upon the testing of all animals which supply milk. This is not in the interests of the dairymen, but in the interests of the community. We believe our stock owners should take action at the coming session of the legislature to secure more just action in the matter.

We notice in a Middle West paper reference to a trip of several hundred miles through Kansas on which the writer had seen many alfalfa mills standing idle. No explanation is given, so we cannot utter any warning other than that if this matter is being overdone in the Middle West it might be well to observe caution in the establishing of more of these mills in our state. They certainly have produced a profitable feed and many stock owners are using alfalfa meal continuously, but if Easterners are finding overproduction along this line, let us Westerners use care.

The oldest bee man in the state has just been reappointed bee inspector of Orange county. Many of our readers know him, and will appreciate the action of the Republican board of supervisors in appointing a Democrat to this position. The man is Mr. J. E. Pleasants, and his candidacy was endorsed by practically all bee keepers of Orange county.

"I do the very best I know how—the very best I can and I mean to keep doing so until the end. If the end brings me out all right what is said against me won't amount to anything, if the end brings me out wrong ten angels swearing I was right would make no difference."—Abraham Lincoln.

A German colony is being established near Live Oak, Sutter county.

Agricultural News Notes of the Pacific Coast

Northern California

English walnuts are being planted extensively near Live Oak, Sutter county.

Fruit growers of Paradise, Butte county, will build a large packing house.

With hops hopping from 14 to 20 cents a pound, those who have held their last crop are jubilant.

Yuba City, Sutter county, produced raspberries, watermelons and tomatoes for Christmas dinners.

The Schmeiser Manufacturing Company, at Davis, is making extensive improvements on its factory.

Butte county stock men report grass on the ranges growing better than they feared from the rain shortage.

As a missionary box to the poor children of San Francisco, Oroville Sunday schools shipped a supply of Butte county oranges.

Montague, Siskiyou county, has offered forty acres and $1,000 in cash to the university for the establishment of a demonstration farm.

The Sutter County Farmer reports extensive planting of orchard trees about Yuba City. English walnuts especially will be planted.

The horticultural commissioner of Placer county finds some orchards infested with brown apricot scale, and is recommending spraying.

The Oroville Register maintains that orange-producing lands of Butte county are held at altogether too low prices, considering their profitableness.

The State Horticultural Commission will make an extensive exhibit of beneficial insects at the Citrus Fair to be held in Sacramento beginning January 13.

The Horst Hop Company, with large holdings near Wheatland, is reducing its acreage to the extent of a hundred acres. Dairying will take the place of hop growing.

Orange growers of the Butte County Citrus Association are receiving their first dividend of $1 per box on the first pool of fruit for the season. This distribution amounts to about $10,000.

While spraying the brooder with coil oil to eradicate mites, a poultryman at Petaluma caused an expensive brooder to be burned to the ground because of not extinguishing fire in the stove.

One poultryman near Haywards, Alameda county, made big money this year in fattening geese after the style that is carried on in France and Germany. The San Francisco market took them at long prices.

The officers elected to control the Farmers' Union of Chico, Butte county, for the coming year are as follows: George O. Miller, president; Edmund Gale, vice president; W. J. Van Arsdale, secretary and treasurer.

A small fruit grower at Chico, Butte county, has a variety of raspberries which are bearing heavily at this season. The bushes are yet loaded with green fruit, and he hopes he has a very valuable addition to small fruits.

Central California

Many sections of the valley show activity in plowing, notwithstanding the dry weather.

Another quarter of a cent has been added to the market price of seedless raisins, the price now ranging near 3½ cents.

One turkey grower of Tulare whose flock consisted of two fowls has a net profit of $107 from the year's product of the two.

Lindsay, Tulare county, shipped during the past twelve months 53 cars seedlings, 128 cars Valencias, 1,141 cars navels.

It is estimated that the orange growers of the Lindsay district were paid between January 1, 1910, and January 1, 1911, $739,840.

The officers of the apple annual at Watsonville are planning for a rousing meeting of all the stockholders to be held January 9.

A grain warehouse at Lois, Tulare county, has been sold to fruit men, and will be transformed into an orange packing house.

A grapevine was exhibited at the Tulare county citrus fair which showed on one graft placed last spring an aggregate growth of 500 feet.

Arthur E. Miot of the Tulare County Board of Trade, is delivering daily illustrated lectures in the Chamber of Commerce rooms, Los Angeles.

The Department of Agriculture of the Hanford Union High school is planning for the setting of many trees and shrubs on the high school grounds.

Irrigators near Turlock are watching the watershed of the Tuolumne river, lest power or irrigation companies deprive them of some of their rights.

Claim jumpers have been busy with land which the Southern Pacific has claimed for years. This is because of the news of the government suit against the company.

Monterey hopes to interest the San Joaquin Valley in its effort for a state appropriation to aid in the construction of a breakwater and to improve the shipping facilities of that harbor.

A second car of Turkish tobacco has just been shipped from Exeter to New York. It is understood that this will be made up into genuine "imported" Turkish cigarettes in New York City.

The Peoples Ditch Company which irrigates much land in Kings county, is strengthening and improving the old weir. About 340 feet of a new weir has also been practically completed.

A mass meeting recently held at Fresno endorsed a plan by which a $100,000 corporation was formed for handling and selling next season's raisins, but it is reported that the promotion is not yet past the talking point, or at least not to the point of the paying in of coin.

Great interest is being taken by property owners on the west side of the San Joaquin Valley in the agitation for an irrigation district. The scheme is immense, covering over 3,000,000 acres.

Southern California

The cotton gin at Imperial is running full time on first-class staple.

Upland, San Bernardino county, has an orange 23 inches in circumference.

One rancher in Imperial county reports two bales of cotton to the acre.

Bostonia, San Diego county, is proving an excellent lemon producing section.

The beet planting in the section of Simi, Ventura county, has been completed.

The California Eucalyptus Company is contemplating construction of a hardwood factory at Oxnard.

The Orange County Dried Fruit Association reports about nine carloads of last season's fruit yet unsold.

Dehesa in the El Cajon Valley, San Diego county, has shipped out some remarkably fine apples this season.

A large tract of land in San Bernardino county in the so-called desert section is to be reclaimed and subdivided.

The Hemet Canning Company has strong commendation for its large output of canned fruits put up this last season.

Poultrymen of El Cajon Valley, San Diego county, are planning a poultry exhibit during the last of this month or first of next.

The canning factory at Anaheim, Orange county, is planning for extensive improvements and the biggest run ever next season.

B. A. Woodford of the Southern California Fruit Growers' Exchange, addressed the Farmers Club at Covina last week on methods of marketing.

The directors of the San Diego World's Fair are planning for a great celebration the coming spring at the time of breaking ground for the 1915 fair.

The work of the Ventura county Lima Bean Growers Association in advertising its products in the East has materially aided in securing better prices.

The highway commission of Orange county has recommended the calling of an election on the question of issuing $1,400,000 worth of bonds for good roads.

The Whittier Walnut Growers Association has disbursed over $300,000 to its members for its 101 cars of nuts shipped. The price received was 15 cents a pound.

Several land owners of the Imperial Valley not having water stock in the irrigation company are entering suit to force the granting of water for irrigation of their lands.

One of the biggest water filings in the section was made last week in Massacre Canyon in the San Jacinto mountains. It was for 25,000 inches. The water will be used in the watering of lands in San Jacinto, Moreno and Alessandro.

Supervisors and good roads admirers from several counties recently made inspection of one of Los Angeles county's good roads through San Fernando and to the Newhall tunnel. It was declared to be an exceptionally fine piece of roadway.

The Coast

Fresh ranch eggs are selling at Portland, Oregon, at 42½ cents.

Christmas turkeys sold in the Portland market for 25 and 26 cents.

Spokane has been shipping extensively of apples to the New York market.

Tillamook, Washington, is planning for its first county fair to be held next August.

Coos county, Oregon, is shipping apples to San Francisco and receiving good returns.

Some hop buyers of Washington have oversold and are now scurrying to buy sufficient stock to cover.

A delegation of Northern Montana interests is urging endorsement of Milk River reclamation projects.

The annual meeting of the Puyallup and Sumner Fruit Growers Association will be held at Puyallup next Saturday.

Four carloads of Fresno scrapers have been shipped to Lower California to be used in levee building along the Colorado.

Seventy thousand bushels of wheat changed hands at Lewiston, Idaho, recently at prices ranging from 67 to 69½ cents.

An Ashland, Oregon, fruit grower has made an excellent sale of apples in London, England. The average per box was $1.54.

A huge concrete warehouse is being built at Cashmere, Washington. It is to have storage capacity of 100,000 boxes of apples.

Eighteen thousand acres will be watered by the electric transmission line of the Pacific Power & Light Co. at Walla Walla, Washington.

Farmers of Burns, Oregon, are asking the state legislature to pass a bill granting bounty for jackrabbits, which are becoming a serious pest.

Farmers near Nelson, British Columbia, are petitioning for privilege of issuing debentures for the purpose of establishing a local irrigation system.

The orders for nursery stock, especially apple trees, about Spokane, Washington, in fact, all of the Inland Empire, are heavier than any preecding year.

An irrigation scheme which will cover 10,000 acres of fruit land in Okanoogan county, Washington, is promised by a power company at Loomis.

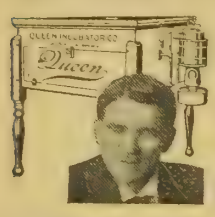
Warehousemen at Nez Perce, Idaho, are busy because the cold weather has put the roads in the best condition and farmers are delivering great quantities of grain.

The Farmers Union at Walla Walla, Washington, has rejected all grain bag bids, the lowest being $5.80. The price paid last year was $5.47½. The farmers realize that jute is higher than last year but insist not to that extent.

A new cattle-feeding grain has been developed at the Wyoming Experiment Farm which is a cross between Russian spelt and American wheat. It is called ommer. It is declared to be drouth-resisting, and yields ninety to a hundred bushels per acre.

Go In and Make Money

Poultry offers the surest, easiest way of anything that's open to you. Don't waste *all* your time considering. Go in and *make* it win.



I have started over 61,000 people the Queen Incubator Way. May I do the same for you? Get my offer on

The 1911

Queen

Incubator

The incubator that makes money for poultry raisers. Take one and *try it* for 60, 90 or more days and prove for yourself that it is the hatcher I claim it to be. I take all the chances. *I pay the freight*, too, and give a 10 year guarantee now. It is my way of showing people what they can accomplish with Queens.

Get the 1911 Queen Book

The New Queen Poultry Guide and Catalog is larger and finer this year than ever. It tells how to make money with poultry and how to get a Queen Incubator on the most generous terms ever offered. Let me send you my great book to tell you about Queens and Success. An infallible guide; no other book like it. *Free and postpaid.* Address

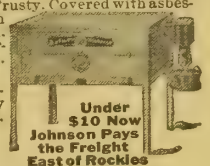
Wickstrum, The Queen Incubator Man
Box 53, Lincoln, Neb.

Johnson Gets Only 7 Per Cent Profit on 100,000 Old Trustys

Johnson says tell you to sure send your name this time for his 1911 price—less than $10 for Old Trusty, freight prepaid (East of Rockies)—based on 100,000 capacity and only 7% profit.

My 1911 Book Tells You

Take 30, 60 or 90 days' trial. Remember Johnson's 10-year guarantee on Old Trusty. Covered with asbestos and again covered with handsome sheet metal. 80% or better hatches guaranteed. Simple and sure.



Send Name

My big 1911 book has hundreds of photos. Every page a poultry sermon. Write postal to

Practical Poultry Culture

THE HOUDAN—THE PRIDE OF FRANCE.

The Houdan is the pride of France, and well may the French poultrymen feel proud of it. It is one of the few breeds that is both useful and ornamental. There are other French breeds—and they are good ones, too—but of the entire class there is not one that seems to be so well adapted to the changeable climate of America.

In the minds of many, there is but one objectionable feature, and that has been the cause of its not being at the head of the imported practical breeds—the presence of a crest. This crest lops over the eyes to a certain extent, making them, as chicks, easy prey to hawks, and as fowls, susceptible to colds when caught out in heavy rainstorms.

Otherwise, the Houdans are hardy, and besides are excellent layers, giving a large white egg. As table poultry—well, they have few, if any, superiors. The writer has bred this variety for a number of years, and can testify from experience to their fine practical qualities.

As we have stated, the Houdan is held in high esteem in its native country, being classed by the Frenchmen second only to one other breed, the Creve Coeur, which, however, for some reason or other, does not stand our climate so well.

"The Dorkings of France" is a title given to the Houdans, owing to their large, heavy, short legs, their five toes on each foot, and the small, light bone and a remarkable absence of offal.

As chicks, the Houdans mature rapidly, feather early and are strong and vigorous.

Crossed with older breeds, the Houdan imparts its good qualities to a high degree. The writer, some years ago, made a cross of a Houdan cockerel on Partridge Cochin hens, and also a Houdan cockerel on Light Brahma hens. The former cross proved to be best for quick growing and plump body, making an ideal broiler, as well as a very attractive roasting fowl.

Mr. Tegetmeier, England's famous authority, says the Houdan fowl has a very bulky appearance, its plumage being black and white spangled; a crest of the same color; comb triple, the outside opening like two leaves of a book, and the center having the appearance of an ill-shaped, long strawberry. With the cock the comb is very large. The legs are strong and of a lead color, with five claws, the two hind ones one above the other. Strongly developed whiskers and beards, both in cocks and hens.

Mr. Tegetmeier continues: "This is one of the finest races of fowls, but its qualities surpass even its beauty. Besides the smallness of their bones, and the fineness of their flesh, they are of an extraordinary precocity and fecundity; they lay large and white eggs, and the chickens are fit for the table at four months old. The weight of adults is from seven to eight pounds, in which the bones figure for one-eighth. The chickens when four months old weigh, without the intestines, about four and a half pounds."

Lewis Wright, another English authority, says he believes the Houdan was created, to a certain extent, by Dorking blood crossed with the Mottled Ancona. They have the size, deep compact body, short legs, and fifth toe of the Dorking, which in form they closely resemble, but with much less offal and smaller bones.

Wright also hints that as some hens, with age, become nearly white, the precaution to avoid this was in crossing with the Creve Coeur. Occasional specimens of Houdans get very large, as heavy as ten pounds for a hen has been attained, but, of course, that is an exceptional case.

Wright then gives this testimony: "Better table fowls are none; the laying powers are great, the chickens fledge and grow faster than almost any breed, and the eggs are invariably prolific—indeed, the ardent Houdan cock requires more hens than almost any other."—American Poultry Adv.

GOOD PROFIT IN RAISING BROILERS.

There is hardly any period of the year when it may be said that poultry needs less attention than at other times, but it's certainly the case that there is a time when the most profit may be made from the poultry yard and that time is winter. It is not necessary to remind anyone that 30 to 45 cents a dozen is a high price for eggs, and that there is a good profit in them at that price. Fewer people, however, realize that there is a big profit in broilers and that broilers can be raised as successfully in winter with the proper preparations and care as they can be in spring, and better than they can in midsummer.

The greatest enemy of old as well as young chickens in winter is not the cold but the wet. We seldom have weather below Maryland that will hurt chickens if it is unaccompanied by rain, and then if the fowls are properly sheltered and protected no damage need result. Birds must be kept in and protected during bad weather, but with the right kind of chicken houses, such as any farmer may build for himself, tight and cold and waterproof on all sides except the southern, chickens will not suffer.

To raise broilers in winter hens must be set in sheltered places and shut up to prevent their leaving the nest for too long at a time. Food and water must of course be kept within reach. After the chicks are taken off they must remain under shelter and be protected from cold winds as well as wet until they are well feathered and able to take care of themselves. It is much better that they be kept under shelter until they are eight or ten weeks old, when they will be ready to market for handsome prices if they are the proper kind of stock and have been cared for properly. Of course if they are kept longer they will grow larger and bring more, but the larger they grow the more feed it takes to make an ounce of meat. Of equal importance with proper shelter is the proper feed for both old chickens and the chicks. If hens are to be expected to lay during the winter months, when eggs are highest, they must be given the kind of food that will make them lay. If they have no pasturage some substitute for it must be provided, for green stuff is one of the first essentials. Sprouted oats are excel-

lent. Ground or shredded alfalfa is a good substitute when the real succulent green stuff is not to be had. Beef scrap has been regarded as the only substitute for the worms, bugs, etc., that form an important part of the bird's food when on range in the spring and summer months. I find, however, that cottonseed meal contains even more protein than the beef and that it is much cheaper and more agreeable to handle. It is entirely too rich to be fed by itself and I feed it one part to two and three of bran and cornmeal mixed, in both wet mash, which I feed in the morning, and a dry mash that I keep before my chickens all the time. I find that the most convenient way to feed my chickens is to feed a wet mash, sometimes varied with grain, swelled oats, etc., in the morning and a feed of grain at night, with the dry mash within reach all the time.

A good feed for chicks is bread baked thick from a mixture of two parts cornmeal, one part bran and one part cottonseed meal. Dry bran may be kept before them practically all the time.—Inland Farmer.

DOCTORING SICK FOWLS.

If there is any one thing upon which poultrymen generally agree it is to at once remove from the flock all fowls which show signs of any form of illness. Get them out at once, before you wait to learn the nature of the disease. There can be nothing gained by leaving the sick birds among those which are well, and it is possible to threaten the entire flock.

Another thing: If you want to try to doctor sick fowls, all well and good, but don't conclude that you have effected a cure and then put the convalescent fowls back with those which are healthy. Keep them separated, and it will be found that it is inadvisable to put the birds together at all.

The safest plan is to keep the birds separated all the time, from the moment you discover any signs of illness. If this is done, a lot of trouble will be avoided.—The Fruit Grower.

SUNFLOWER SEED.

Sunflower seed is highly recommended by some people as a ration for poultry on account of the kernel containing oil that is said to be highly beneficial in improving the quality of color and gloss on the plumage of the fowls, as well as being an aid to poultry during the moulting process.

The facts are that sunflower seed is more than 90 per cent waste matter, the hulls being difficult to digest and of little or no feeding value. A few sunflower seed may be of some benefit to poultry, but fed in large quantities they would be a detriment rather than a benefit—Pacific Homestead.

DUCKS.

Ducks grow faster when they have no pond or water to swim in. However, they must always have a plentiful supply in troughs. Have their troughs set up on platforms, so they cannot puddle up the soil alongside. Ducks do not continue as profitable breeders much beyond the third year. Very old geese cannot be made palatable for dressed poultry, but ducks can be quickly fattened into palatable food at almost any age. If taken when quite thin in flesh and fed on rich, fattening foods, they will fill out with juicy, palatable meat in a few weeks, and make fairly good market fowls. If the ducks are kept in the farmyard with other fowls, put their grain food

in a pan or other suitable vessel, and pour water on the grain until it is covered an inch deep. By such arrangement the hens cannot rob the ducks, while the latter eat with greater ease by having their food under water. But each fowl will thrive better, however, if kept to itself. The duck generally lays at night. It thrives best on soft, succulent food. Strong, vigorous birds can be successfully bred at four years of age. Properly fed, at eight weeks of age green ducks will weigh nine pounds to the pair; at ten weeks they should weigh ten to eleven pounds to the pair. The market term "green duck" is a late innovation. The cognomen is applied for the reason that the birds have not yet matured. Pekin ducks are great layers, but are of no account as mothers; consequently, if they cease laying and remain on the nest, shut them up, feed them well for a few days, and when they are turned loose they will soon begin to lay again.—Indiana Fowl Fanciers' Journal.

Teach the young chickens to scratch as early as possible by scattering small grain among the litter.

CORRECTING DEFECTS.

The subject of mating is one of much importance and one that is understood by few. The men who have achieved the highest honors are the few who have studied carefully and constantly the matter of points and have had their specialties. The successful breeders of one variety (and few have achieved greatness with more than one breed) begin to study their matings the preceding summer and fall, and watch the development of the chicks, that they may not only get the feather, but vigor and size. It would be useless for us to attempt here anything more than some general pointers, as we have neither the space nor time to direct the mating of all varieties. First study the Standard (it is not infallible, but it is the best we have), and get the ideal shape and color fixed in your mind. Find in what section your birds are most deficient, and try to remedy that by mating to the other extreme. This can usually be done through the male. Solid colored birds are much more easily mated than others, yet must receive care. If the combs of the strain you now have are too large, use a male with a small, low comb. If their legs are too dark or too long, tails droop, backs too long, wattles too short, wrinkled, or uneven; ear-lobes, if white is required, are streaked or edged with red; if red is required, the much despised white blotch appears. These defects can be effaced, perhaps not in one year or two years, but persistence and study will do it. The breeding of high-grade stock requires care, study and vigilance. It requires, also, association and comparison with others, and interchange of ideas and knowledge. One may learn something by visiting with other breeders and exchanging ideas.—Wolverine Poultry Journal.

TO INCREASE PROFITS.

It is a very bad policy to feed the hens nothing but corn; but it is being done by many. Feed a variety, feed grain in litter, making them work for all they get, and do not forget green food. It may be a little extra work, but is cheaper and more profitable.

Fresh turned earth has great powers of absorption of filth and the cultivating of the poultry runs is advisable. Even if your space is small for runs, by frequent turning of the soil you are assured of sanitary conditions if you do it.

Gather the eggs often, this assures fresh eggs, has a tendency to keep hens from broodiness. If they are allowed to remain in the nests until six to ten have accumulated the hens soil them more. It is better to gather eggs two or three times a day the year around.

Cleanliness should now, in particular, at this season of the year, be the paramount issue or duty with every poultryman. Do not let filth and droppings remain in the poultry house, dirty scratching litter and nesting material. A little neglect now will give you poorer results later on and a big crop of lice.

You can spade or plow in oats in the poultry runs with a profit. Considerable grain will be scratched out, some will be eaten just as it sprouts and other grains will shoot forth a stalk and it will all be devoured by the hens, with a fancy profit. The stirring of the ground will keep the place more healthful, the hens busy.

Do not neglect to clean the poultry house often. Filth is a breeder of disease. Filth is the profit-eating germ of the poultry business. If you want to make money from your poultry attend to this little duty of keeping everything clean and in a sanitary condition around the poultry houses and yards.

It does not matter what your aim is in the poultry business, even if it is only a few for the house, you can not afford to raise mongrels. Get some eggs from a reliable breeder, start right, and raise good poultry, even if it is only a few. It looks better, sells better, tastes better, and will cost you no more to raise them.—Poultry Pointers.

ADVERTISING SUGGESTIONS.

It is impossible to make hard and fast rules regarding advertising. Probably some advertisers have found that the following suggestions do not always produce results; yet experience gives strong testimony. One advertiser complains he is not getting results. Inspection of his "ad" reveals that it is simply headed "Stop!" By reading the fine print which follows, you can learn what varieties he offers, and other details. But ten chances to one the man who wants Rhode Island Reds is looking for and will read those "ads" in which that breed stands out as the most prminent thing. In advertising merchandise, a peculiar or unusual heading is regarded as desirable to attract the reader's attention, probably upon the supposition that the reader is not looking primarily for the articles mentioned in the "ad," and yet the dealer wants to reach that reader and tell his story so well the reader will buy. Generally this is not true of poultry advertising. The reader wants a particular breed or variety; he has not time to go through several hundred "ads." He simply glances over each page, and whenever his breed appears in type heavy enough to be noticeable, he reads that "ad" to see if the advertiser has the exact thing he is looking for. It seems wise for an advertiser in a poultry journal to restrict the wording, and use enough space to enable the printer to put the name of the breed in large, bold type. Freak advertising or headlines not pertaining to poultry do not apear to be profitable in this line. Remember these statements when writing "ads," and you will be less likely to have reason to feel that advertising does not pay.—Profitable Poultry.

Study the effects of care and feeding with your poultry, and try to work out some poultry problems for yourself.

White Leghorns

A Standard Strain of Great Layers and Great Winners. None superior. Prices reasonable. Booklet descriptive of our stock and farm, containing recipe for mixing the best and cheapest egg-producing mash, sent free for stamp. Eggs, stock and baby chicks for sale. Also a grand lot of cockerels. On a separate farm, we have an extra fine lot of Buff Orpingtons, from which we can furnish stock, eggs and baby chicks at popular prices.

MODEL POULTRY FARM

Irvington, Alameda County, California

Chickens For Profit

The present status of the POULTRY MARKET means a big return on a poultry investment. Whether you have a large place or a small one you can profitably employ a portion of it for poultry.

Last month eggs retailed at SIXTY CENTS A DOZEN. Even at that price there were thousands of dozen imported from the east.

California consumes more poultry and eggs than she produces, but not more than she can produce. The state is ideal for poultry. Mild climate, good soil, large range and big demand.

Poultry raising is easy, pleasant and profitable. Your son or daughter can take care of the chickens, make his own spending money, bring you a good return on the investment, besides furnising the table with fresh eggs and tender, tasty meat.

We supply everything for proftable poultry raising, including Poultry Foods, Incubators, Brooders, Poultry Remedies and supplies of all kinds.

Write for catalogue and special instructions to fit your particular case.

Irrigation and Forestry

THE WORK OF THE GOVERNMENT IN FOREST PRODUCTS.

The United States is now facing the problem of forest conservation which must be solved by every county some time during its history. The original American forests were unexcelled anywhere in the world. Not only did they cover a vast area, but they were characterized by trees of great age and size, and by an unusual variety of valuable species. Heretofore we have drawn chiefly upon the original supply of timber, and the bulk of the lumber used in this country today is still from trees over 150 years of age. In spite of the rapid rate of cutting and the destruction of forests by fire, ample supplies have been made available by the opening of new regions through the extension of railroads and through the development of logging engineering. The process, however, cannot be continued indefinitely. Already the end of the virgin supply of timber is clearly in sight, and all thoughtful men who are familiar with the conditions appreciate that there is before us a problem which very profoundly affects the welfare of the country.

The problem of forest conservation must be worked out from two standpoints; first, by securing the greatest possible economy in the utilization of forest products, and, second, by producing new supplies through forest growth.

At present, there is a great loss in the utilization of forest products, and the production of new supplies is entirely inadequate to meet the requirements of the people in the future. Within recent years great progress has been made in the protection of forests from fire. The loss from that source has been greatly reduced, although there is still an enormous amount of destruction of young growth by fire, and in some sections fire has almost entirely prevented forest reproduction. One of the most important aims of the forestry movement has been to bring about not only the protection of standing timber from fire and other agencies, but also the replacement of forests as they are cut and the establishment of denuded lands.

Forestry, however, does not stop with the growth of trees. It concerns itself equally with the disposal and utilization of the products. The two branches of forestry, forest utilization and forest production, are inseparably related. The market for products is one of the factors most controlling the selection of species to be grown and the methods of handling woodlands for forest growth. The study of forest products is, therefore, one of the most important lines of work of the Forest Service.

The fundamental purposes of the work of the Service in products are, first, to bring into use the greatest possible amount of the products of the forests with the least possible waste, and, second, to place these products to their best use. In other words, the Service aims to aid in making the material which can be obtained from the forest meet in the highest degree the real requirements of the people. This broad principle is the foundation of the work which will be done at and in connection with this laboratory.

In its work in products, the Forest Service keeps in view two objects: first, direct aid to the various wood-using industries, and second, forest conservation in its broadest sense.

The interest, co-operation, and support given to the Service by practical men engaged in different industries is proof of the apreciation of the work in products which has been done and is projected.

The science of forestry in this country is at its very beginning. While the American species of trees are well known botanically, the study of their life-history, their behavior in the forest, and their possibilities of production has only recently made much progress. It is equally true that our knowledge of the products of the various species is still very inadequate.

The first necessity is to determine the fundamental properties of the various woods. This information is essential as a foundation for the study of the suitability of the different species for specific uses. At the present time there are many species which are little used or not used at all because of ignorance of their properties or prejudice against them. Many of the common commercial species are for the same reason confined to only a few of the possible uses. It is the aim of the Forest Service to show the possibilities of all the species and to demonstrate the uses to which each is best adapted.

The demonstrations at the laboratory today have illustrated many of the special lines of work and the methods of conducting the investigations. You have seen the methods of studying the fundamental physical, mechanical and chemical properties of wood.

A further aim of the work at the laboratory is to study the methods of handling wood products so as best to adapt them to certain purposes. Studies will be carried on at the laboratory to show the behavior of the various woods under different conditions. One of the important problems is to determine the influence of different conditions of moisture on the strength, durability and other characteristics of wood. This work will form the foundation for the investigation of the best methods of seasoning wood in order to bring the products into the market in the most suitable condition for their various uses.

The next problem is the study of how to treat wood products so as to improve their natural qualities. One

Why Not Do It Right--"Let the Hart-Parr Do Your Work"

Experience teaches that the proper way to prepare land to get best results, is to plow deep, tear up the clods and reduce the surface as fine and level as possible, so as to prevent evaporation of moisture.

Proper preparation of the seed bed is one of the things which goes a long way to assure at least a fair return, even in the driest year.

So, why not do it right?

"It is up to us to tell you why ours is the best,
But it is up to you to put it to your test."

THE "MODERN FARM HORSE" will furnish the power. The plows can be sunk just as deeply as desired and the heavy traction pulverizers will leave the land level and in shape to take in and hold every drop of moisture which falls on it.

Some sections which cannot be properly farmed by the use of horses will return good crops when handled with a tractor, because in that way the land will be treated as it should be.

DO IT RIGHT—

Buy a Modern Farm Horse Now.

Let us tell you more about this "Modern Farm Horse," and its advantages on your farm. Mail us a postal card—we will do the rest. Two sizes, 30 H.P. and 45 H.P.

ROEDING & WOOD NURSERY COMPANY

EXETER, TULARE COUNTY, CALIFORNIA

of the most important lines of work at the laboratory will be the study of the treatment of wood to prolong its life. There is required in the first place a thorough study of the various preservatives. Then follows the investigation of the methods of treating the different species with reference to their peculiar specific characteristics.

There are a multitude of problems of wood utilization, but among the most important are the investigations of the possibilities of the different species for the manufacture of paper, and the study of the by-products which can be obtained by various processes. The laboratory is especially equipped to make these investigations.

I have given special emphasis to the fundamental and scientific character of the work to be done at the laboratory. Every investigation, however, is directed to the solution of some practical problem. Many experiments are conducted at the laboratory on a commercial scale, or commercial tests are made in co-operation with private concerns. In many cases, the work at the laboratory is supplemented by extensive field experiments. Through co-operation with private companies and trade associations, the investigations will not only be brought into the most practical lines, but the results will be given an immediate application.

The branch of forest products has been established at Madison. The laboratory is the center of its work. It concerns itself, however, with the whole field of forest utilization. There are special branches of its work in the various districts of the national forests of the West, and there are two subsidiary laboratories, one in the state of Washington, and one in Colorado. It is the design to bring the work into the closest relation with all the wood-using industries. The determination of the fundamental facts and principles of wood-utilization is the first step. To secure the practical application of those principles requires the assistance and co-operation of all those interested in them in a practical way.

There has been a most gratifying co-operation with the Forest Service by the different railroads, lumber companies, paper companies, woodworking concerns, and trade associations. I wish to take this occasion to express the appreciation of the Forest Service for this co-operation and assistance.

From the standpoint of conservation, the work of the government in forest products is of great importance. When one examines the losses in the utilization of wood products, one finds that these begin in the woods. Many species are not cut at all; often the trees left uncut deteriorate rapidly, or blow over, or are injured in logging; frequently long tops containing a large amount of low-grade lumber are left in the woods; and many logs only partially defective remain on the ground. The cause of this seeming waste is the condition of the market. The lumberman seeks to take out only what he can dispose of at a profit. It is to his own interest to take out of the woods just as much as he can possibly utilize, because every increase in amount of marketable material removed reduces the cost of production and increases profits. The amount of waste in the woods is therefore definitely governed by market conditions. In exactly the same way it is the condition of the market which causes a great loss in the manufacture of lumber. Close utilization follows good markets.

It is the market, also, which most powerfully influences the problem of forest production. The better the market, the greater is the value of the timber; an improved market means a correspondingly increased inducement to protect the forests from fire; there is an increased value of immature and young growth; and a correspondingly greater justification for investments in holding and protecting cut-over lands for the production of new stands of timber.

The work of the Forest Service in products will have a direct influence in the long run on market conditions. The development of new uses of wood will bring into the market species and grades not before merchantable. The uses of wood for by-products will reduce waste and enable the lumberman to use material now frequently left in the woods or wasted at the mill. The extension of the use of treated timber will enable the marketing of the less valuable species for uses now requiring the most valuable. There will thus be a constant tendency to extend the market and to decrease the loss in utilization all along the line from the stump to the manufactured product.

There are, however, other factors influencing the market which will not be directly touched by the investigations at the laboratory. These factors must not be overlooked in the consideration of the relation of the market for forest products to conservation. Problems connected with the methods of logging and manufacture of lumber, grades and sizes of lumber, rates for low-grade lumber, the car-stake question, etc., concern conservation. In some of these problems, the Forest Service can be of assistance through its work of products.

One of the most serious problems, however, in the whole realm of forest conservation is that of over-production of lumber. In some sections of the country more lumber is being manufactured than is needed. There is, in consequence, a poor market for the

(Continued on Page 31.)

The Most Successful Plowing Outfit Built

An Avery Double Undermounted Engine and a Cockshutt-Avery Engine Gang Plow

Avery Steam Plow Outfit in Operation

MANY farmers have already found out that their Avery Plow Outfit is one of the best money-making investments they have ever made in the way of farming machinery. Besides those who have bought Avery Plow Outfits for their own use, a large number of threshermen and others are buying them and making plowing a business in addition to their threshing, sawing, shelling and other work, thus adding a large amount to their profits.

The construction of the Avery Outfit is such as to give it a record of wonderful success in all parts of the world.

Power That You Can Depend Upon

The Avery Undermounted Engine is a steam engine. It can be depended upon to do the work right along. You can increase the power when it comes to a hard pull, and decrease it when the plows pull lighter.

The construction of a steam engine is simple. Anyone can operate it. There are very few parts to break or get out of order, and it does not take an expert to keep it going or keep it in repair.

The Avery Engine Is Undermounted—Patented—A Design Much Superior For Plowing Purposes

In the first place it lasts longer than others because all the machinery is mounted on an independent frame work, and the boiler is relieved from all pulling strains.

You have no loose brackets, leaky bolts, or other such troubles with this engine.

In the second place an Avery Undermounted Engine has two cylinders, which is the only correct construction of an engine for heavy work such as plowing. Besides this the pull of the cylinders through the gearing and back to the load is in a straight line on this engine, while with other styles it is down from the top of the boiler at an angle.

In the third place the Avery Undermounted Engine is much more convenient to handle because of the fact that all of the machinery can be reached while standing on the ground, without having to climb around over a hot boiler.

For all-around work, plowing, hauling or belt work of any kind, there is no engine built today that can compare with the Avery Undermounted Engine. The only engine of its kind on the market. This engine is built in five sizes—18, 20, 22, 30 and 40 H. P. and will burn wood, coal, straw or crude oil as fuel.

The Avery Steam Plow Outfit

The Cockshutt-Avery Engine Gang Does First Class Plowing

It has had a wonderful success. Each plow is independent and is thus free to follow the variations of the ground without interference from any other plow. Each plow will turn a uniform furrow at a uniform depth either deep or shallow.

Built To Stand Up Under Hard Work

Has an extra strong steel frame, double beams and a heavy cast shank. Many of those now using Cockshutt-Avery Gangs have tried out other makes but have found that they would not stand up under the work. This plow will not only do good work in stubble ground, but also in tough breaking, hard dry plowing and in stony ground. It is built in five sizes—5, 6, 8, 10 and 12 gang, with either stubble or breaker bottoms.

You Should Find Out All About the Avery Steam Plow Outfit

About the engine that is built Undermounted. The only one that is like a Railroad Locomotive. An engine that will *last longer*, *pull harder* and *handle easier* than any other. You should find out all about the kind of work which the Cockshutt-Avery Gang Plow can do for you. Write for special circulars showing Avery Steam Plow Outfits at work in the field. You can see from these pictures just what kind of work this outfit will do.

Send your name on a postal or letter for our special steam plowing circular, and if you are figuring on buying, say about what size outfit you would be interested in.

Questions and Answers

THE EDITOR AND STAFF

Questions to be answered in this department should be received at this office one week before reply is expected. Write plainly on one side of the paper and sign full name and address. Unsigned communications receive no attention.

Balanced Ration for Cow.

Kindly tell me if the following proportions make a balanced ration that will produce the most milk. I am feeding my cows each morning and evening: Bran, 1½ pounds; middlings, 1¼ pounds; Calfalfa meal, 1½ pounds; cocoanut meal, 1½ pounds; as a mash, quite wet, with all the red oat hay that they will eat three times a day. Not having a silo or green pasture, am compelled to feed mill feeds.—B. A., San Jose.

The following table may help you to estimate the feed now given to the cows. The only criticism I should make is that the number of different feeds mixed in mush make it necessary to buy in small quantities, and this is more expensive than buying in larger quantities. Bran and alfalfa meal are nearly alike in composition, and one or the other could be left out. The available nutriments in the feeds given are as follows to the hundred pounds:

	Protein.	Carbohydrates.
Wheat bran	12.2	39.2
Middlings	12.8	53
Oat hay	4.3	46.4
Cocoanut meal	15.6	38.3
Alfalfa hay	11.9	39.9

By moving the decimal point two figures to the left of these numbers they are reduced to one pound, and from that the ration can be figured accurately. It is well to remember that different cows need their food in varying proportions, and that the fixed rule does not always work perfectly on that account. Alfalfa meal varies more from the analysis than any of the others. The bran is usually the more expensive feed, and is used more as an appetizer. If alfalfa meal is cheaper, it will take its place. Chopped alfalfa hay, say two pounds a day, added, will take the place very nicely of the bran, and if soaked with the cocoanut meal over night, adds succulency to the feed. The amount to feed depends on the amount of milk the cow gives, and is figured out about as follows:

	—Lbs. Daily.— Protein.	Carbohydrates.
Cows yielding 11 lbs. of milk daily	1.6	10
Cows yielding 16.5 lbs. of milk daily	2.0	11
Cows yielding 22 lbs. of milk daily	2.5	13
Cows yielding 27.5 lbs. of milk daily	3.3	13

Eight to ten pounds of a cow's rations should be given in the form of long hay to aid her in raising the cud to rechew the feed.

Canning Peaches.

Which clingstone peach is in most demand and brings the highest price at the canneries? Also, which freestone? I want to set out several acres on the Chino ranch.—F. A. R., Chino.

This was referred to Mr. George H. Waters, of the Pomona Cannery, who is as well qualified as anyone in the state to answer the question. He writes:

"I think I am pretty well posted on what the canners are wanting in the peach line. They have settled on two varieties, the Phillips cling and the Lovell freestone. These are the finest varieties we have in this country, beyond any question whatever, for all purposes. Both varieties have very small pit and are prolific bearers. The peach men can make no mistake on these two kinds."

Fencing Against Gophers.

I noticed a question from a subscriber at Santa Barbara on the subject of fencing out gophers by a buried fence. A good many years ago I helped build a buried gopher fence four feet deep. It was a failure. Since that time I have known them to go under a cement storm ditch about seven feet deep. This is no guess, as I ran water into the hole, and it came out farther down the ditch on the other side. They regularly go under the North Fork canal here in Highland, which is about four feet deep and nearly as wide.—D. J. Aplin, Highland.

Book on Goats.

In response to an inquiry in a former Cultivator as to a book on goats, Miss B. A. R. Stocker of San Luis Obispo sends in the following: Bulletin No. 68, Bureau of Animal Industry, U. S. Department Agriculture; Information Concerning Milch Goats; Price 15 cents. Address Superintendent of Documents, Government Printing Office, Washington, D. C. This is exceedingly interesting and valuable. There are also two English books by H. S. Holmes Pegler, "The Book of the Goat" and "Goat Keeping for Amateurs," which can probably be obtained from Chas. Scribner's Sons, New York.

Squab Turkeys.

How old should turkeys be to be marketed as "squab turkeys," and do you know any attractive ways to prepare them for the table, besides broiling them?—"Amateur."

During our experience of over twenty-five years in connection with poultry affairs, we never heard of squab turkeys, and doubt if such have ever been of commercial significance. There are, however, turkey broilers, which are birds having attained a weight of from three to four pounds. In so far as preparation is concerned, the same practice as is followed in the case of broiler chickens would hold good.

Age of Ducks.

How can one tell old ducks from young ones, and what to feed them?—Mrs. M. Chatt.

Our correspondent evidently means birds that have reached maturity, when, of course, the general appearance of both old and young is much alike. Indeed, the distinction is purely relative. Bone and frame become firmly fixed in the older birds, beak becomes hardened, the web tougher, veins under wing more pronounced, etc.

Water Power.

How many gallons of water per minute does a miner's inch amount to? How much electrical power can be developed from a 30-inch stream with vertical fall, also 40-foot stream?—L. B. Ventura.

An inch of water is practically nine gallons per minute. Thirty inches would equal 270 gallons, which at the approximate figure of eight pounds per gallon would equal 2,160 pounds. With a 20-foot fall, this would equal in weight a column of water 20 feet

AVERY THIRTY H. P. UNDERMOUNTED

OIL-BURNING STEAM TRACTION ENGINE

☞ FOR SALE CHEAP

This Engine is equipped with all approved time and labor-saving devices. It has been slightly used for experimental work only and is warranted to be in first-class condition.

AVERY COCKSHUTT PLOW—ten 14-inch steel bases, especially for this engine—will be sold cheap. It is brand new—has never been used. The Cockshutt Plow has won first prize at all international plowing contests for the last three years.

Both Engine and Plow will be sold below factory cost, and we will be glad to mail you description and prices. This is a real opportunity to buy a first-class outfit at big saving over the cost of inferior goods.

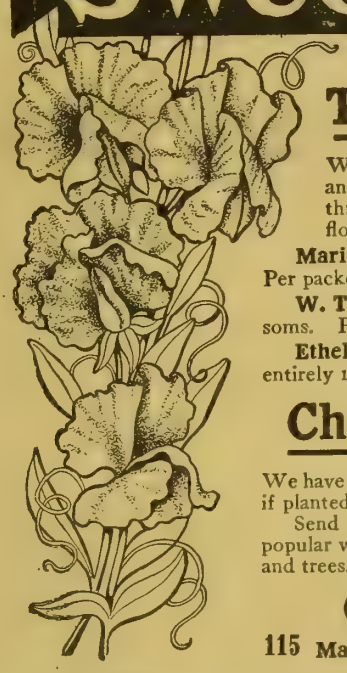
Sweet Peas



Three Giant Spencers

We are the largest growers of Sweet Peas in the world and ship our seeds everywhere. For 1911 we have three new varieties, all are of enormous size, bear four flowers to a stem, and blossom most freely.

Marie Corelli: a wonderful rose crimson Sweet Pea. Per packet, 15c.

W. T. Hutchins: very large cream and faint pink blossoms. Per packet, 15c.

Ethel Roosevelt: lemon and straw with blush flakes; entirely new. Per packet, 25c.

Christmas Sweet Peas

We have several varieties which will blossom at Christmas time if planted now. Per packet, assorted Christmas varieties, **10c.**

Send for our complete catalog illustrating all the new popular varieties of sweet peas, as well as all our seeds, plants and trees. Mailed free to any address.

Deep Well Pumping For Irrigation.

The past season has demonstrated more than ever the practicability and superiority of the Pomona Deep Well Pumps. It is fully proven that it is possible to lift large quantities of water from very deep wells with a surprisingly small amount of power. It has usually been considered that a plunger pump is only good for a 35-inch stream on a lift of say 200 feet, but the Pomona Manufacturing Company have demonstrated that it is no longer necessary to use a centrifugal pump, with its wasteful usage of power, to get a large quantity of water out of the ground, as this company is manufacturing extra large size cylinders including 12, 13, 14 and 16 inches in diameter, and capable of lifting from 50 to 100 miner's inches of water. Not only that, but they are prepared to go down after it to depths of 300 and 400 feet if necessary.

They have one plant at Claremont where the water stands 390 feet below the surface and the pump has a total lift of 450 feet, delivering 45 miner's inches of water with 60 H. P. on the motor, and doing it easily. There is another plant in Ontario lifting 60 miner's inches 300 feet with a 60 H. P. engine.

The parts below the surface have been so perfected that they are perfectly reliable and are giving as little trouble as it is possible for a machine to do. Other pump makers, noting the wonderful success of the Pomona Pumps, are trying to imitate them, promising something just as good, but they are only imitators and have not the knowledge or ability to make their claims good.

The Pomona Manufacturing Company has a large plant at Pomona, the only one in Southern California, devoted almost exclusively to manufacturing Plunger Pumps. They are a reliable establishment and are here to stay, to make good their guarantees and to supply your wants in the way of extras or assistance. Their machines and apparatus have been tried out and their value fully demonstrated.

Anyone needing pumping machinery should send to them for catalogs, or visit them in person.

high, or a total of 43,200. This divided by 33,000 pounds, number of pounds per second-foot which will create one horsepower, gives 1.3, the theoretical horsepower of the one inch with the 20-foot fall. The 40-foot fall would simply double this amount, giving a horsepower of 2.6. This, as noted, is theoretically correct, but no motor has 100 per cent of efficiency. Sixty per cent is the most common, and 90 per cent is the limit of practically perfect machinery. It is safest to figure on a 60 per cent basis. This would yield .8 horsepower from the 20-foot fall and 1.6 from the 40-foot.

We may remark that the new standard inch adopted some years ago is 1½ cubic feet per minute. This would equal 11.2 gallons per minute, but the former figure given is for the inch of common usage in California.

White Holland Turkeys.

Where may I secure a setting of White Holland turkey eggs?—Subscriber, Surrey.

We have no White Holland people advertising in the Cultivator at the present time, and will ask our subscribers who know of breeders of this stock to inform us. (Two ne wads this week. See liner page.)

Salt Bush.

I am sending a plant which I would like to have named. On my ranch is a large patch of Bermuda. I withdrew water from this, hoping to kill it, but it persists in living. I have observed, however, a bush of this weed which I send growing without irrigation, and whenever it comes up in the Bermuda it spreads, hugging close to the ground and killing out the Bermuda underneath. The plant seems to be an annual growing from a single root, with branches extending in all directions. It is easily eradicated, so that I do not fear it, but wish to know whether, in addition to its Bermuda-killing capacity, it has other good qualities, especially as a green manure.—B. L. Y., El Centro.

This plant is atriplex microcarpa, one of the common California salt bushes. It is of some value as a stock food, and would, of course, add humus to the soil if plowed under, but it does not have the nitrogen-gathering properties of the legumes.

Sore Mouth.

Have a cow that carries a mouthful of partially chewed alfalfa hay, occasionally ejecting the same, only to repeat the process. Kindly advise as to cause and treatment.—Subscriber.

I should suspect sore mouth or a bad tooth to be the cause of this trouble. Examine and treat the same carefully. Feed soft feed until the trouble passes away.—M. E. S.

Alfalfa Tea for Calves.

What additional feed can be given to young calves as a substitute for skim milk, of which we have about one gallon per day for each calf?—Subscriber.

Alfalfa tea has been often recommended by Mrs. Sherman for this purpose. Full directions for its preparation will be found on page 549 of the Cultivator of December 1, 1910.

Alligator Pears.

What kinds of soil and what general conditions are favorable to alligator pears? Would they do well here in Exeter, Tulare county?—Subscriber, Exeter.

The avocado or alligator pear will usually do well in all situations where oranges or lemons thrive, at least so far as it has been tried. Some have questioned as to whether the more arid and warmer valleys of the interior could grow this fruit successfully. So far as we know the trees which have done best are within a few miles of the ocean where there is no excessively warm weather. In addition we have heard of trees planted in warm valleys which did well under lath house but died when lath house was removed from them. From these reports we would advise experimenting before extensive planting.

Sycamores.

Can the American and European sycamores be grown from cuttings?—Subscriber, Corona.

They can. On the place of the writer is an American plane tree grown from a cutting broken from a large tree in the Arroyo Seco three summers ago, which is now between fifteen and twenty feet high.

Influence of Bud.

If a seedling of midsummer variety of peach is budded from a late variety such as the Bilyeu, will the fruit be hybridized or affected by this stock?—R. E. H., Lakeside.

The fruit on the graft or bud should be exactly the same as that on the parent tree from which it was taken. In other words, the stock has no influence on the variety.

Fertilizer for Berries.

What is the best fertilizer for Mammoth Blacks and how much per vine is necessary? Vines make strong growth but the berries are small. Should the new sprouts be cut off during the crop season?—L. C. N., Redlands.

The best fertilizer for these berries is stable manure applied heavily around the plants and cultivated and worked in during the season. If preferred to use commercial fertilizer, we would use the ordinary or complete fertilizer well scattered about a large growing bush. It is well to keep down the sprouts which are continually coming up during the fruiting season. The small size of berries may possibly result from shortage of water supply.

Substitute for Milk.

What can I use as substitute for curds for young turkeys?—Subscriber, Ballard.

Cotton seed meal has been recommended, but owing to its toxic properties, especially when fed to hogs, it has been deemed a questionable food. Cocoanut oil meal is safer and probably would prove satisfactory. Be sure it is fresh, for if rancid it will prove dengerous. Blood meal is also good, in fact a most excellent food.

Dynamometer.

Is there an instrument made which may be attached to plow or wagon to which team may be hitched and which will indicate the amount of power required to pull the implement? If so, where may such instrument be obtained?—Subscriber.

Such an instrument is made. A full description of it may be seen in King's Agricultural Physics. It is in line with the implements carried by farm implement companies, but we assume it would not be in stock with most implement houses. We understand that some training is necessary to understand its use.

Bermuda.

I have a few patches of Bermuda grass six feet in diameter in peach orchard. Will a five-gallon can of gasolene to each of these patches kill the grass, and will it kill the peach trees where the grass surrounds them? Is it best to use gasolene, kerosene or distillate for this purpose?—Subscriber, Fresno.

The best way to eradicate small patches of Bermuda like these is with cultivator and mattock. The use of distillate sprayed on the grass during exceptionally hot weather is sometimes helpful but we would fear effect

Eucalyptus Seeds

In large or small quantities, 33 kinds to select from. Write for free pamphlet "Eucalyptus Culture." It gives full directions for sowing the seed, raising the plants and planting out into the field, together with descriptions of all the leading species, giving their uses and the localities to which they are adapted. Sample packets 15c each, 2 for 25c, 4 for 50c, 9 for $1.00. Choice Flower, Garden, Tree, and Palm Seeds, Roses, Flowering Plants, etc. Catalogue mailed free upon application.

on trees, as indicated above. Distillate is preferable to either gasolene or kerosene as it is vastly cheaper and has fully as good killing qualities, perhaps better than either. Eradication the fumigation is to be favored as there is no doubt of benefit to the orchard.

...ed Scale.

I send leaf which shows some disease affecting my orange and lemon trees. What is it and what will cure it?—Subscriber, Los Angeles.

The leaf sent was badly infested with red scale which can be successfully handled by fumigation. See issue of the Cultivator of November 3rd, which will give general outline of the work.

Ceratostophaga to Improve Adriatics.

I have White Adriatic fig trees which do not produce first-class fruit. Will it be best to graft over trees?—C. K. H., Pasadena.

We do not believe the fertilization of White Adriatic figs with pollen from the caprifig by means of the ceratophaga or fig wasp would materially benefit your fruit. It is worth a trial, however. We presume one way of improving the value of your fruit is to graft over to the Smyrna variety.

Pushing Buds Up.

Some budders slip the buds up, claiming that the sap flows up the center of the heart and down between the bark and wood. Others slip the bud down, claiming the sap flows up between the bark and the wood and that a cross cut diverts the sap and the bud starves.—J. M. C., Alhambra.

Probably ninety-nine hundredths of the budding of citrus trees is by pushing the bud down. However, the statement of those who push the bud **up,** that is, that the flow of sap is from the root to the leaf in the heart of the tree and the elaborated plant food flows down between the outer bark and the cambium layer, is correct. So the theory of those who push up has the preference, but in practice there is no appreciable difference and the pushing down will doubtless generally continue.

Spray for Lemons.

I have orchard infested with black scale and am about to spray it with five per cent mixture of distillate. I have tried this in a small way with hand pump, and it kills the young scale, but I have silver mite and red spider. Will this distillate be effective against them?—C. H. H., Pasadena.

You will certainly run a great risk in putting the ordinary low-grade distillate mixture on your lemon trees in strength of five per cent. Two or three per cent of the higher grade 28 degree tree distillate is all that is perfectly safe on the growing lemon. Of course, at this season of the year where the trees are entirely dormant, the stronger mixture may be pormissible. The safer spray would be the distillate or kerosene emulsion given in the Cultivator of November 3rd. These are numbered 13 and 14 in the list of formulas.

Veterinary

Answers in this column by Dr. Fred G. Matthews, are without charge. For immediate mail answer remit $1.00. In writing questions give full symptoms or particulars of injury of animal.

Tuberculin Test.

My cow has a cough which aroused my suspicion, and I had her tested for tuberculosis. The temperatures were as follows: 2 p. m., 101.8 degrees; 6 p. m., 100.4; tuberculin injected; 6 a. m. (second day), 100.4; 8 a. m., 100.2; 10 a. m., 100.6; 12 m., 103.4. Does this rise of temperature indicate tuberculosis?—Inquirer.

A rise of less than two degrees over the highest temperature of the day before injection, and that rise appearing eighteen hours after injection, does not constitute a typical reaction.—F. G. M.

Cough.

A mare, in good flesh, has a cough. A remedy would be thankfully received.—Subscriber, Lodi.

Purchase from druggist twelve ounces of Fowler's solution and give the mare a half ounce twice daily in the feed. Also have prepared sixteen powders, each containing a half drachm of potassium iodide, one drachm gentian and one drachm nux vomica—one powder to be given twice daily with the solution.—F. G. M.

Chronic Scours.

A horse, age ten years, has scours, the discharge beginning in the first half-mile drive, and increasing to such an extent that the animal is almost exhausted at the end of a five-mile journey.—Subscriber.

Ask your druggist to obtain four ounces of gallogen and divide it into twelve equal powders. Give one powder in the feed three times a day. Repeat after one week if not completely cured.—F. G. M.

Warbles.

A heifer has lumps the size of a marble along the backbone. The hair stands erect over each lump. What is the cause, and how to remove it?—Subscriber, Fresno.

In each of these lumps is the grub or larva of the gad fly of cattle. By pressing on each side of the lump with the thumbs the grub may be forced out. These grubs mature and emerge late in the spring or in early summer, hence if it is not possible to expel them now the effort may be deferred till springtime. Destroy the grubs—they mature into gad flies, which pester cattle.—F. G. M.

"Blind Teeth" in Pigs.

What is the cause of blind teeth in pigs and how may they be treated? Do they cause sores to appear on the outside of the head and face? Where can I get a book on the hog?—Subscriber, Grub Gulch.

Hogs are subject to dental troubles but I have no knowledge of a disease known as "Blind teeth." Abscess formations at the root of decaying teeth sometimes break and discharge from the surface of the face, but I know of no disease of the teeth which is the cause of ulcers or sores on the skin of the head. Books on the diseases of swine may be had from Orange Judd Co., or may be secured from The Cultivator.—F. G. M.

G. Harold Powell is now in charge of the work of the Citrus League.

SQUIRRELS BRING DEATH.

(Continued from Page 3.)

benefits to be gained by destroying the pests.

The Federal government, in aid of the state health board, has made a liberal appropriation, and will render further assistance by the detail of experienced medical officers whose time will be given wholly to the work; it is realized that the problem cannot be solved in a year, or at any fixed time; therefore, plans have been made to place the eradicative procedures on a permanent basis. With this object in view, a thoroughly equipped camp will be established in the squirrel infested region, where practical instruction will be given in field methods. Although designed primarily for the training of our own employes, this camp may be utilized by farmers and others who may desire such instruction. The expense of the camp will be charged against the Federal fund.

THE CHRYSANTHEMUM.

If you have none of the most beautiful and most popular of all potted plants, the chrysanthemum, which is in full and glorious bloom during late fall and early winter, you have missed something extraordinary in the flower line. The chrysanthemum has become a general favorite because the plants are so hardy, the blossoms so pure and large, and because it comes into full bloom late in the fall and early winter when blossoms of any kind are most welcome.

The chrysanthemum with ordinary handling will come into blossom about Thanksgiving time, and it serves admirably for decorating the feast table for the occasion. The blossoms as cut flowers will last a full month in a vase in a cool room if the ends of the stems are clipped and fresh water supplied frequently.

The way to secure the cuttings is to allow the plants to blossom and fade, then cut off the old stems about an inch above the soil. New shoots at the base of the old stems will soon come out, and these when about four inches high are cut for rooting. Root them in a box of moist sand, potting in two-inch pots when roots have formed, and set the young plants in the open garden in summer for growth.

The chrysanthemum is a gross feeder, hence the soil in which it grows must be very rich. Supply abundance of manure. When potted for fall blooming, use rich soil and bonemeal to stimulate large growth and blossoms. Supply plenty of moisture, with good drainage. Train to a single stem or many branches, as desired.

Imperial county cotton pickers received one cent per pound.

"Let There be Light."

—PAT HENRY, before the battle of Bull Run.

We are not sure that our old friend Pat has been correctly quoted, neither do we know that he was anywhere near Bull Run during that memorial event, but we do know that every Rancher, Miner, Dairyman, Stableman and Teamster on the Pacific Coast should be in possession of at least one of our Vehicle Headlights, here illustrated.

There are times when a good, strong light is almost indispensable. It is needed around the barn, the thrasher, the harvester, on the gang-plow, on your wagon or buggy when driving over rough roads, the ranch, the mine or the dairy.

A Boesch Vehicle Headlight is worth a dozen ordinary hand lanterns. They are well made, strong and durable, each one is fitted with a highly polished silver plated parabolic reflector which concentrates the rays of light with remarkable brilliancy. The body is finished in a rich glossy black with polished brass trimmings, and for appearance it is first in order of handsome lamps. It embodies all our latest improvements, and for efficiency as a light producer it is without equal. This is the Headlight that caused the passing of the State Law prohibiting the hunting of wild ducks by artificial light. It is being used by nearly every Fire Department on the Coast and in many of the large Eastern cities.

Do not be led into buying a cheap, inferior lamp. It won't pay. This one is the result of forty-two years' experience in the business. It is home industry, and we guarantee satisfaction. It is made in 6, 8 and 12-inch sizes, measurements across the face.

We also manufacture many other styles of Headlights, Lamps, Lanterns, etc., too numerous to mention.

Write for Catalogue and full particulars of lamps or lanterns that you require.

When writing to advertisers mention the Cultivator

Timely Ranch Suggestions

A SYSTEM OF SOIL CULTURE.

By A. M. Ten Eyck, Superintendent Fort Hays Branch Experiment Station, Kansas.

So far as cultivation is concerned, there are three principal steps in the conservation of soil moisture:

1. The soil must be loosened to a considerable depth in order to prepare a reservoir to receive the rain and to carry the water downward into the soil. This is accomplished by deep plowing or by discing unplowed lands.

2. The water which is carried downward into the subsoil must be brought back again into the surface soil where the seed is germinating and the roots are growing, and, to accomplish this, a good connection must be made between the furrow-slice and the subsoil, and this is the purpose in the use of the sub-surface packer.

3. Finally, in order that the water which is drawn up toward the surface by capillary action may not reach the air and be wasted by evaporation, the upper two to four inches of soil must be kept mellow, in the form of a soil mulch, which is accomplished by frequent cultivation, and this is applicable not only to corn and other intertilled crops, but also to wheat and other small-grain crops.

Systematic Tillage.

Discing the land before plowing puts the soil of the furrow-slice into better condition to reunite with the subsoil when the furrow is turned over. The smooth, hard furrow bottom, as left by the ordinary plow, is unfavorable to the proper union of the furrow-slice with the subsoil. In order to cause a more complete union of the furrow-slice with subsoil, the bottom of the furrow may be loosened by means of a shallow subsoiling attachment to the plow.

Such a system of culture is intended to favor the conservation of soil moisture, and is thus especially adapted to regions where a limited or irregular rainfall makes the most careful methods of soil culture necessary in order to store and conserve the water in the soil and get the most use from it in the production of crops.

Tillage and Fertility.

The principles stated above have been known and practiced more or less for a long time, and are mostly included in the Campbell system of culture. H. W. Campbell was among the early apostles of dry land farming in the West, and has perhaps done more to call the attention of Western farmers to the necessity and advantages of thorough cultivation of the soil than any other investigator. The method of culture advocated by Mr. Campbell is, in fact, simply good tillage and thorough cultivation of the soil at the right time, in the right way, and in a systematic manner.

Good farming pays, everywhere. The writer believes in the practicability of thorough tillage and good cultivation on every farm, and the increase in crops by such farming will more than pay for the extra labor, and in a series of years should leave our farms in a better state of fertility and more capable of producing crops than may result from the careless and shiftless methods of farming which are yet too commonly practiced by many farmers throughout the West. The greatest problem in Western agriculture today is not how to get larger crops out of the soil for a few years, but rather how to produce paying crops every year and at the same time maintain the fertility and productiveness of the land.

Implements and Methods.

It is not necessary to have extra machinery in order to successfully practice the system of culture outlined above. The only implement required or recommended which is not in general use on every well-equipped farm is a sub-surface packer.

The use of the packer is most essential on late spring plowing when the purpose is to plant at once after plowing. It is not so necessary to use the subsurface packer on fall plowing which is not intended to be planted until the following spring, but for sowing fall wheat, if the plowing preceded the sowing by a very short interval, the subsurface packer may be used very advantageously.

When land is allowed to lie for a considerable period after plowing before the crop is planted, the settling of the soil, together with the cementing due to rain, usually causes the soil to repack and firm up to a sufficient extent to make a good seed-bed.

The subsurface packer is a hard-running machine, and it costs much more to use it than it does to use the common harrow, or even the disc harrow. Thus, at the Kansas Experiment Station we have adopted the practice of early plowing whenever it can be done, in preference to subsurface packing, using the harrow or the disc immediately after plowing. However, the principle involved in the use of the subsurface packer is correct, and the lighter the soil and the greater its tendency to remain loose and mellow, the more necessary becomes the use of the subsurface packer or similar implement, in order to prepare a proper seed-bed.

In plowing under trash or manure, subsurface packing, by pulverizing the bottom of the furrow-slice, sifts the soil through the coarse trash and causes a better union with the subsoil below, so that the capillary water may be drawn up into the surface soil, whereas, if a heavy coat of stubble or manure plowed under in this way is left without packing or pulverizing, the furrow-slice is apt to dry out, and the crop that is growing on the land may be injured by a short interval of dry weather. By setting the discs rather straight and weighting the harrow, a disc-harrow may be used as a substitute for the subsurface packer, resulting in a pulverizing and firming effect at the bottom of the furrow-slice. Very often, however, good plowing, with the proper use of the common harrow, may largely accomplish the results required in preparing a proper seed-bed. It is usually advisable to weight or ride the common straight-tooth harrow in order to cause it to stir and pulverize the soil deeper and prevent the "slicking" effect which is apt to result from light harrowing.

Deep Plowing.

Some types of soil can be plowed deeper than others, and the writer believes in deep plowing, at least every few years. The deeper loosening of the soil not only makes a larger reservoir to catch the rain, but it gives more

room in which the soil bacteria may ha[ve]lop and prepare the plant food.

It is known that certain bacteria in the soil have much to do with the preparation of the food for plants, and experiments have shown that these bacteria are found largely in the surface six to nine inches of the soil, or in that part of the soil which is turned with the plow and stirred with the cultivator; thus deep plowing favors the development of the bacteria and the preparation of more available plant food than is the result from shallow plowing. The depth and frequency of plowing will vary according to the nature of the soil, a light or sandy soil requiring less depth of plowing and less frequent plowing than a heavy, compact, clayey or "gumbo" soil.

A New Method.

A new method for preparing the seed-bed for wheat is now coming into general practice in Western Kansas. The plan is to list the ground with the ordinary corn lister as soon after harrowing as possible. The lister furrows are run about three to three and a half feet apart, very much the same as when the lister is used for planting corn. Later, when the weeds have started, the soil is worked back into the lister furrows by means of a disc harrow or disc sled or disc cultivator.

The disc sled has just recently come into use, and is considered a preferable implement to the disc harrow. This sled is constructed with extra large discs, especially for this purpose, but the sled may also be used for cultivating corn. The sleds are made to cultivate either one or two rows.

Several cultivations are usually required by the disc harrow in order to bring the field into good seed-bed condition. Once over with the disc sled is usually considered sufficient, the further work necessary to prepare the seed-bed being given with the common harrow or other cultivating implement.

In a dry climate this method of preparing the seed-bed has these advantages: The cultivation of the land soon after harvest tends to conserve the moisture already stored in the soil. The furrowed land is in good condition to catch and store the rain, and the later cultivation clears the land of weeds and leaves a mellow soil mulch to conserve the moisture which has been stored in the subsoil. The early and continued cultivation of the soil favors the action of the bacteria and the development of available plant food.

By practicing this method of farming the farmer may cultivate a larger area early in the season when the soil is in good condition to cultivate, whereas if it had been necessary to plow the whole area, some of the land might have become too dry to plow well. Likewise the later plowing leaves the soil too loose and not in good seed-bed condition.

By several cultivations with the common harrow, after the ridges have been worked down with the disc sled, the soil may be well pulverized and firmed and put into good seed-bed condition. In fact, as will be observed, the larger part of the seed-bed area has not been loosened deeply, and even with little or no rain to firm the seed-bed, the subsurface soil remains firm and the seed-bed is in ideal condition to start the wheat.

The Soil Mulch.

In the ideal system of culture the purpose is to keep a mellow soil mulch on the surface of the land all of the time, not only during the growth of the crop, but also in the interval between harvest and seeding time. Thus, after the crop is planted, the land is kept cultivated with the weeder or harrow in order to break the surface crust and conserve the soil moisture, and following out the same principle, the harrowing or work with the weeder is continued after the grain or corn is up, and during the growing period frequent cultivation is required for inter-tilled crops.

Discing After Harvesting.

After the crop is harvested the cultivation is not discontinued, but the surface of the soil is loosened as soon as possible after the crop is removed, by the use of the disc harrow, and thus the soil is kept continually in a condition to not only prevent the loss of water already stored in the soil, but also this same condition and mellow surface favors the absorption of rain and largely prevents the loss of water by surface drainage.

The smooth, finely-pulverized surface left by continuous light harrowing really defeats the purpose of the cultivation, since soil in such condition will shed heavy rains, causing a waste of water which should have been stored in the soil, and the surface often becomes too fine and compact, preventing the proper aeration of the soil and producing an unfavorable seed-bed condition. Thus, during the interval between crops, it is sometimes advisable to use the Acme or the disc harrow in order to keep the surface of the soil open and mellow.

Harrowing Wheat.

The weed harrow or weeder is probably better adapted for harrowing wheat or other small grain than the common straight-tooth or slanting-tooth harrow. The weeder is somewhat objectionable on account of the wheels. When the ground is reasonably firm the common harrow may be used without injury to the wheat.

The writer questions whether it is necessary to continue the harrowing after the wheat covers the ground well, unless heavy rains firm and puddle the soil, destroying the mulch of mellow soil. Usually this will not occur.

In a single trial, wheat was harrowed when it stood five or six inches high and had stooled so as to nearly cover the ground, and the mulch thus produced was still in evidence at harvest time. In this experiment the ground was harrowed twice on the same day. The yield of wheat on the harrowed plot was, on the average, three bushels per acre above that from the field adjacent, not harrowed. This experiment, with others, was carried on at the North Dakota Experiment Station with spring wheat, and it was observed that wheat harrowed before it had stooled much was injured in stand and gave a lower yield of grain than wheat not harrowed.—Dry Farming Bulletin.

Offerings for turkeys all over the valley are not so satisfactory as the Thanksgiving prices.

Improved Superlative Red Raspberry Plants—Largest raspberry in cultivation. 100 plants, $5.00. Send for description. William Richard, 438 River St., Santa Cruz, Cal.

FARM LANDS FOR SALE.

For Sale—By owner, good farm land, $50 per acre, in Merced County, 9 miles from Merced and ½ mile from station on S. P. and 4 miles from La Grande on Santa Fe. This land is a rich, sediment soil, situated in the Artesian Belt and an abundance of water is thus assured. Is level and all under cultivation. No alkali, and is suitable for figs, corn, alfalfa, beans, and all farm crops. Will subdivide in lots from 40 to 1000 acres. This land is very cheap at the price. In fact, it is only one-half the price of other land in same locality. For further particulars call or address Paxton, 612 Lankershim Bldg., Los Angeles.

For Sale—A 20-acre farm for $20 cash and $20 a month; possession now; $90 to $125 per acre; your crops pay for the land. Rich, level land for alfalfa, oranges, almonds, grapes, cows, chickens; abundance of ditch water, for irrigation, for $1 an acre a year. Where else can you get this? In Oakdale Colony, near good town and railroad station, climate delightful. T. Wiesendanger, 207 S. Broadway, Los Angeles, Cal.

For Sale—815 acres in San Luis Obispo County. A typical dairy ranch. Plenty of wood, water, irrigable land, buildings, fenced and cross fenced. Orchards, vineyards, oranges, lemons and walnuts do exceedingly well here. Forty acres of land suitable for these. Price $21 per acre. For further particulars apply to Mrs. F. A. Clink, Pozo, Cal.

For Sale—The Fresno Meadows Colony is now opened for settlement in lots of 40 acres or more with water at $50 per acre. This is an opening price and is made to induce settlement. Arrangements can be made so that the first payment will carry the deal indefinitely. Call or write at once. Green & Webb, Gen. Sales Agents, 406 Laughlin Bldg., Los Angeles. Phone A8284.

For Sale—$1,500, good income property, 87½ acres, 1½ miles from postoffice. Summer resort, famous mineral springs; trout fishing. 20 acres of good bearing vineyard and fruits of all kinds and garden. Good house and other buildings; fine scenery; fine well and springs; timber of all kinds. Address E. V. Stafford, Lidell, Cal.

For Sale—San Joaquin Valley Land. 200 acres of the finest alfalfa or tree land in the state for $105 per acre. Easy terms. Will sell in 20's or 40's, or all to purchaser. At present land is all in barley. Land is all level and have plenty of water. Address Geo. H. Hudson, Fresno, Cal.

60 Acres in Santa Clara County. A splendid dairy ranch. Good barns, dwelling and water supply. ¾ of it in excellent stand of alfalfa; close to railroad; one hour's run from San Francisco. Address 281 North Third St., San Jose, Cal.

Irrigated Land—The famous Gridley Colonies. Improved lands, best homeseekers' proposition in California. Write for particulars. Gridley Land Co., Gridley, Cal.

Cuba—Most productive soil. Delightful and healthful climate. Ample rainfall. Cheapest transportation facilities to the world's greatest markets. Particulars free. Sanderson, 13 Palace Building, Minneapolis.

For Sale—Near Lancaster, Cal., bargains in improved and unimproved land. Also relinquishments for sale or trade. Some homestead land. A. S. Burnham, Box 451, Lancaster, Cal.

Apple Orchards—Large and small, in the only apple producing section in California. The greatest section west of Missouri River. Write for booklet. Geo. W. Sill & Co., Watsonville, Cal.

For Sale—20-acre fruit ranch, Ontario. 10 peaches, 10 apricots in full bearing. Suitable for oranges. No trade. M. E. York, Owner, R. F. D. 2, Chino, Cal.

TURKEYS.

White Holland Turkeys—Gobblers $7 and $10; young hens, $5. Booking orders now for eggs and poults. Mrs. B. Hocking, Guasti, Cal.

For Sale—Thoroughbred Mammoth Bronze turkey toms, spring hatch. Only a few left, all fine, large, well marked birds. Have two female Scotch Collie pups left, pedigreed stock. Mrs. A. C. Wisegarver, San Fernando, Cal.

For Sale—Young Mammoth White Holland Turkey Toms. Fine large birds of the celebrated J. C. Fischel Strain. None better as thoroughbreds, also excellent to cross with the Bronze for the market. Price $8.00 to $10.00 each. Foreman Bros., Box 213, Corning, Cal.

Special Sale—In order to make room for my breeding stock I am offering the remainder of my thoroughbred Mammoth Bronze Turkey Toms for $6 each. My turkeys are of the best in the state, spring hatch and weigh 20 to 24 lbs., and reach a large size at maturity, as those to whom I have sold stock previously can testify. Mrs. Nellie Hart, Holtville, Cal.

REAL ESTATE.

Dividends not called for are added to the deposit account and earn dividends from January 1, 1911. George Tourny, Manager.

Entomology and Bees

LEGISLATION.

At the next annual convention of ne State Beekeepers' Association it s expected that the committee ap-ointed at the last meeting, having in harge the drafting of a bill relative o apiary inspection, will have com-leted its labors, and make a report. And it is hoped that that report will e made before the full house, and not n committee. For if the draft goes p to Sacramento, it will carry the mpression of embodying the desires f at least a majority of the beekeep- of the state, and that impression ould be no illusion. The committee ould state just what its bill is for, A neral, and paragraph by para-raph, in particular, and everybody hould be given the floor who wants it, it for or against the measure, or ts of it. The text of the bill whose ge was attempted two years ago, ugh it was claimed for it that "the keepers of the state" wanted it, known only to a few, a very few en. And it is, indeed, difficult to understand how any practical beekeep- could have been guilty of endors-ng some of its provisions, particular-y those dealing with requeening work.

In general, in this matter of law-getting, whatever we do, let's go slow, and let us steer clear of state social-ism; of endorsing the creation of offi-ces and the appointment of officials "in charge of apiculture," beekeepers and all. The leaning of the former bill was that way. True, since one beekeeper's carelessness or incompe-tency may injure his neighbor by having diseases spread abroad from his apiary, some legislative easement seems good. But it is probably just as well not to expect much from any-thing coming from Sacramento. We have had bee disease legislation in this state for over a quarter of a cen-tury, yet only season before last thousands upon thousands of colo-nies of bees went to ruin from dis-eased brood in the San Joaquin alone. It is highly questionable if the more stringent rules of the former bill, if applied, would bring any noticeable relief into that stricken valley, or into any like situation.

In fact, the truth of the matter—i. e., the failure of our twenty-seven years of legislation to eliminate bacil-lus alvei from the domain of apicul-ture—seems to be that we are yet wanting in a truly scientific method of procedure in the case. For, certainly, nobody will contend that burning hive, bees, comb and all is anything but the work of despair, just as burning a house to get rid of bedbugs would be.

It cannot have escaped the most or-dinary of observers that certain places or localities are entirely free, even immune, from foul brood; some have it sometimes, but it goes or cures easily, and some seem simply inca-pable of getting rid of it entirely, no matter haw energetically fought. The hills and mountains and dry, gravely mesas of the interior have no disease, at least hardly ever. But along the coast, the low, moist valleys and bot-toms of the interior, there is always trouble. There are no statistics on that matter, and nobody can tell for certain what makes the difference. But the difference is a fact, and to know its causation would probably also in-dicate the means of cleansing our bees.

In Germany, the land of taking pains, they also have the foul brood just as they have it on the shores of the Po, notwithstanding the prevailing notion that Italian bees are immune. Several years ago the government of the former country was petitioned to enact some protective measures, so beekeeping wouldn't go to ruin. Well, it has not done so yet. Not because it ignored the matter; far from it. The value of the honey bee in any scheme of successful agriculture is too well known for that. It started work on the petition at once—not, in-deed, in making laws, but in finding out all about the subject. The bio-logical section of the Imperial Health Office was instructed to begin experi-ments, to gather data, to ascertain everything bearing on the subject, and then to report. About three months ago the government informed the offi-cers of the central beekeepers' society that it stood ready to co-operate with them in formulating a bill that would afford protection.

Eventually we, too, will have to gather knowledge before we shall ob-tain success. With our inspecting system already in running order, we can do that easily. And if Berkeley is willing to co-operate, we shall need very little help from Sacramento.

In the way of a tentative proposi-tion, the following is here offered. Let inspectors be furnished with blank question sheets, one for every apiary visited, which they shall be obliged to fill out to the best of their knowledge. The sheets should bear a date, the name of the place and of the owner, then the size of the apiary, race of bees, their state of health and the general appearance of the apiary. In addition, the topographical condi-tion of the location, the water and nectar sources, and all like matters. After signing his name to it, the in-spector should return the papers to the county office, and the latter should be obliged to mail them to the uni-versity, where the forms should have been designed in the first place. At the university the information thus gathered should be entered onto curve sheets, systematically. A com-parison of them, finally, will yield sure net results. Five years of that work will make us masters of the situation. —Henry E. Horn.

The queen takes no care of the eggs that she lays, nor of the young bees. She leaves all that to her daughters, the workers. She does not even feed herself.

When queens come from a distance through the mails in a jaded condi-tion, it would be a great advantage if they could at once be released upon the combs, but this very jaded condition is against her acceptance.

At this time of the year, do not give any syrup thinner than two and one-half parts of sugar to one of water, boiling hot; and it should be well stirred.—Gleanings.

The queen is all-important to a col-ony. If your queen is good you are sure of a crop if the other conditions are right.

STOP! LOOK! and LISTEN!

WE PAY THE FREIGHT.

Bean Power Sprayers

Are Easy to Handle

They're built exceedingly light, are very compact, and set low down. They can be hauled without trouble where many power outfits would be absolutely useless.

The advantages of a Bean Power Sprayer are demonstrated at their best in densely planted, wet, or hilly orchards. Every outfit is thoroughly tested before it leaves the factory—and we back up every sale with a guarantee that settles every doubt a buyer may have.

There's a Bean Outfit for every size orchard—the Giant for the largest—Challenge for medium size orchards—and the Pony for the smaller ones. The principal difference is in capacity. All are strong, efficient, simple in construction and operation, and are noted for easy accessibility of parts.

SEND FOR NEW BEAN CATALOG.

It's the most complete book we ever published. In it are illustrated and described all Bean Power Sprayers, Hand Pumps, Sprayer parts, accessories, materials, etc. A copy free for your name.

General Household Notes

THE MAN WHO WINS.

The man who wins is the man who works—
The man who toils while the next man shirks;
The man who stands in his deep distress
With his head held high in the deadly press—
Yes, he is the man who wins.

The man who wins is the man who knows
The value of pain and the worth of woes—
Who a lesson learns from the man who fails,
And a moral finds in his mournful wails—
Yes, he is the man who wins.

The man who wins is the man who stays
In the unsought paths and the rocky ways,
And, perhaps, who lingers, now and then,
To help some failure to rise again—
Ah, he is the man who wins.

—Anonymous.

WHEN GORDON ACTED ON IMPULSE.

By S. E. Kiser.

Gordon turned the matter over several times in his mind, and each time he did so he became stronger in the conviction that he had arrived at a proper solution of it. His idea was that people too often neglected to act upon impulse. This was the line of his reasoning:

"What we call impulse is in reality instinct. Our instincts are generally good. The things we do by instinct seldom get us into trouble. More often they get us out of difficulties and bring us happiness. I am going to start out today with the intention of obeying my impulses. If I happen to have an impulse I am going to follow it up. People who stop to dissect their feelings or their impulses before they act seldom do anything. When the cold light of reason is turned upon an impulse the impulse withers and dies. Consequently there is inaction. The happiness that comes of inaction can only be negative in its character. The happiness that is the outgrowth of action is positive. For one day at least I am going to act upon my impulses."

Having arrived at this philosophical conclusion, Roscoe Conkling Gordon crawled out of bed and put on his clothes. As he was fastening his tie he had an impulse. It directed him to remove his clothes and take a cool, refreshing bath. By obeying this impulse he was 20 minutes late getting down to breakfast. Still, he reflected, this was not the fault of the impulse. The bath was a good thing and made him feel much more like doing a day's work than he would have felt without it. The fault was his own in not having had the impulse when he ought to have had it. A new girl came to wait on him when he had seated himself at the table. She was a very pretty girl. It was evident that she had not been long in the waiting business. Her hands were white and small, and she looked as if she might have just started out to earn her own way.

"Perhaps," Gordon thought, "misfortune has overtaken her family, making it necessary for her to do this after having lived all her life in luxury. I'll speak kindly to her." She may need cheer and sympathy."

When she came in from the kitchen to ask whether he would have ham and or a chop he obeyed his impulse by saying:

"This is a fine morning, isn't it?"

"Yes, rather," she replied.

"Are you going to wait on this table right along?"

"I don't know."

"I hope you may."

"Why?"

"Because—you're so pretty."

She blushed and hurried away.

"There," he thought, "I've made her happy. If I had not obeyed my impulse I wouldn't have spoken to her, and she might have brooded all day."

On his way to the city he had another impulse. He sat by an open window in the "L" car, and was busy reading his paper when a good-looking woman got aboard and took a seat directly in front of him. After he had admired the contour of her face he noticed that her filmy waist was not buttoned in the back. She had fastened two or three of the upper buttons and one or two down at her waist, but she had not been able to reach the middle ones. Along came an impulse, which established its headquarters within R. C. Gordon. Leaning forward he deftly caught the soft flaps of the lady's waist and began to button them together.

"I beg your pardon," he said as the lady turned suddenly and fiercely; "I saw that you had not been able to button your waist, and I thought there would be nothing out of the way if I—"

But he was not permitted to finish his explanation. The lady rushed forward to the platform, and seven strong men who had witnessed the outrage began to close in upon Mr. Gordon.

He got off at the next station to wait for another train. When he arrived at the office he was considerably disheveled and 30 minutes late.

Also he was the possessor of a determination to never act on impulse again.—Chicago Record-Herald.

TEXTURE AND FLAVOR OF MEAT.

Although meats vary greatly in the amount of fat which they contain, and to a much less degree in their protein content, the chief difference to be noted between the cheaper and more expensive cuts is not so much in their nutritive value as in their texture and flavor. All muscle consists of tiny fibers which under the microscope are seen to have the form of tubes. These fibers are tender in young animals and in those parts of older animals in which there has been little muscular strain. Under the backbone in the hind quarter is the place from which the tenderest meat comes. This is usually called the tenderloin. Sometimes in beef, and also in pork, it is taken out whole, and sometimes it is left to be cut up with the rest of the loin. In old animals, and in those parts of the body where there has been muscular action, the neck and the legs for example, the muscle fibers are tough and hard. But there is another point which is of even greater importance than this. The fibers of all muscle are bound together in bundles and in groups of bundles

LANGDON'S TOMATOES

"I have tried all the various strains of Earliana on the market, and yours is the only one I have found that meets my idea of what a good early Tomato should be."—Prof. W. F. Massey.

J. M. Myer, Gridley, Cal., writes Nov. 28, 1910: "I tried one-half ounce of your strain of Earliana last year, and alongside of two other crack strains of Earliana yours were ripe a full week first and 25 per cent finer in every way—the finest thing in the line of early tomatoes I ever saw, and I have been at it for thirty years."

By seven years' selection we have produced the Earliest, Hardest, and Smoothest Tomato ever grown. Our location near the Canadian line tends to breed in earliness and vigor, for we have no blight. All our seed is home-grown, is extra large and plump, starting strong, vigorous plants. Send for our circular and get more inside facts.

If you want to be first on your market with perfect Tomatoes that will bring a premium over top-notch prices, plant Langdon's Northern Adirondack Strain of Earliana Tomatoes.

Price: ½ oz. 40c; 1 oz. 60c; 2 oz. $1.25; 4 oz. $2.00; 8 oz. $3.50; 1 lb. $6.00

EUCALYPTUS

The best that 40 years experience can produce, being grown slowly, in the cool atmosphere of the coast, are more hardy and more vigorous than those grown in the hot interior of the State.
Correspondence Invited.
W. A. T. STRATTON, Petaluma, Cal.

by a thin membrane which is known as connective tissue. This membrane, if heated in water or steam, is converted into gelatin. The process goes on quickly if the meat is young and tender; more slowly if it is tough. Connective tissue is also soluble in acetic acid, that acid to which the sourness of vinegar is due. For this reason it is possible to make meat more tender by soaking it in vinegar, or in vinegar and water, the proportions of the two depending on the strength of the vinegar. Sour beef or "sauer fleisch," as it is known to Germans, is a palatable dish of this sort. Since vinegar is a preservative, this suggests a method by which a surplus of beef may be kept for several days and then converted into a palatable dish.

Flavor in meat depends mainly on certain nitrogenous substances which are called extractives because they can be dissolved out or "extracted" by soaking the meat in cold water. The quality of the extractives and the resulting flavor of the meat vary with the condition of the animal and in different parts of its body. They are usually considered better developed in older than in very young animals. Many persons suppose extractives or the flavor they cause are best in the most expensive cuts of meat; in reality, cuts on the side of beef are often of better flavor than tender cuts, but owing to the difficulty of mastication this fact is frequently not detected. The extractives have little or no nutritive value in themselves, but they are of great importance in causing the secretion of digestive juices at the proper time, in the right amount, and of the right chemical character. The digestive tract may be likened to a piece of machinery which is beautifully built and adjusted and is ready to run and turn out its product as soon as a lever is moved which sets it in motion. The flavoring bodies of food, and especially those contained in meat, can be likened to the lever which sets the machinery in motion. Excitants to normal digestion are supplied by other foods as well, but meats, so physiologists believe, are especially important for the purpose. It is this quality which justifies the taking of soup at the beginning of a meal and the giving of broths, meat extracts and similar preparations to invalids and weak persons. These foods have little nutritive material in themselves, but they are great aids to the digestion of other foods.

The amount of the extractives which will be brought out into the water when meat is boiled depends upon the size of the pieces into which the meat is cut and on the length of time they are soaked in cold water before being heated. A good way to hinder the escape of the flavoring matter is to sear the surface of the meat quickly by heating it in fat, or the same end may be attained by plunging it into boiling water. Such facts are known to all cooks, and have recently been studied systematically at the Illinois Experiment Station in relation to the amounts removed and the losses which may be involved in different methods of cookery. Such solubility is taken advantage of in making beef tea at home and in the manufacture of meat extract, the extracted material being finely concentrated by evaporating the water.—Economical Use of Meat in the Home.

The fletcherizing of food has long been practiced by the cow, and the mud bath is nothing new to the hog.

FOOD AND NUTRITION CHARTS.

The recent wide-spread discussion of the high cost of living has aroused great interest in all phases of domestic science, and has greatly increased the demand for the publications of the Department of Agriculture on all subjects relating to food and nutrition.

The department has recently issued a set of fifteen charts on the composition of food materials. These charts are printed from photo-lithographs in six colors, and show in the case of each material the protein, fat, carbohydrate, ash and water contents, and the fuel value expressed in calories. The percentage, composition and fuel values are given in figures, and the relative proportion of each constituent is represented graphically. For example, in the case of whole milk a glass of milk is shown; 87 per cent of the figure is colored green to represent the water content, 3.3 per cent red to represent the protein, 4 per cent yellow to represent the fat, 5 per cent blue to represent the carbohydrates, and 0.7 per cent drab to represent the ash content. The fuel value of 310 calories per pound is represented by printing in solid black nearly one-third of a square one inch on each edge, since one square inch represents 1,000 calories. The figures given for the percentage composition of the various materials are average figures, based upon as many analyses as are available in each case.

The food materials shown in these charts are as follows: 1, whole milk, skim milk, buttermilk, and cream; 2, whole egg, egg (white and yolk), cream cheese, and cottage cheese; 3, lamb chop, pork chop, smoked ham, beefsteak and dried beef; 4, cod (lean fish), salt cod, oyster, smoked herring and mackerel (fat fish); 5, olive oil, bacon, beef suet, butter and lard; 6, corn, wheat, buckwheat, oat, rye and rice; 7, white bread, whole wheat bread, oat breakfast food (cooked), toasted bread, corn bread and macaroni; 8, sugar, molasses, stick candy, maple sugar and honey; 9, parsnip, onion, potato and celery; 10, shelled bean (fresh), navy bean (dry), string bean (green) and corn (green); 11, apple, dried fig, strawberry and banana; 12, grapes (edible portion), raisins (edible portion), grape juice (unfermented), canned fruit and fruit jelly; 13, walnut, chestnut, peanut, peanut butter and cocoanut. Chart 14 gives the functions and uses of food, under the headings "Constituents of Food" and "Uses of Food in the Body." Chart 15 shows the dietary standard for a man in full vigor at moderate muscular work, and the estimated amount of mineral matter required per man per day.

These charts are printed on sheets 21 by 27 inches, of a good quality of paper, and are for sale by the Superintendent of Documents, Government Printing Office, Washington, at $1 per set. The charts will be found especially useful to instructors and students in classes in physiology, domestic science and other branches in which the food and nutrition of man are studied, either in schools or colleges, or in clubs or similar organizations.

PRECAUTION.

Both boys had been rude to their mother. She put them to bed earlier than usual, and then complained to their father about them. So he started up the stairway, and they heard him coming.

"Here comes Papa," said Maurice; "I'm going to make believe I am asleep."

"I'm not," said Harry. "I'm going to get up and put something on."—Canadian Courier.

Save for the Home at the Home Savings

Your Money Grows Here

You draw out more than you put in when you become a savings depositor at this Home Bank. Your profit is definite, sure, constant. Every year is a prosperous one. Begin now. Keep your surplus funds at work.

Extracted amber	.5½@6½
Beeswax, lb	.24@30

Scott, Magner & Miller say:

During the week ending today we have received on the San Francisco market a total of 2,650 tons of hay. It is usual for the month of December to be a little quiet in the hay trade in San Francisco, and this year has been no exception to this rule; in fact, it has been much quieter during this entire month than usual.

With the exception of something strictly "gilt-edged," either of straight wheat in light-weight bales, or of red oat, which can be sold at our topmost quotations, all other grades of hay move off slowly and with no satisfaction to the selling interests.

There has been demand for alfalfa hay, but not in quantities. Arrivals of this article have been remarkably light, and the feeling is somewhat firm, and inquiry is developing from interior points where alfalfa is required at this time.

There has been very little straw shipped into the market recently, but fully enough to more than meet the current demand.

We quote the wholesale prices in round lots on today's market as follows, viz.:

Fancy wheat	.12.50@13.50
No. 1 wheat or wh and oat	.10.50@11.50
No. 2 wheat or wh and oat	.9.00@10.00
Choice tame oat	.11.50@12.00
Other tame oat	.8.00@10.50
Wild oat	.8.00@10.00
Stock hay	.6.00@7.00
Alfalfa, ton	.9.00@11.50
Straw	.40@50

Grain.

Wheat, No. 1	.1.42½@1.50
Barley, fancy	.1.10@1.12½
Barley, good to choice	.1.06¼@1.08¾
Barley, poor to fair	.1.00@1.05
Oats, white	.1.45@1.55
Rye, new crop	.1.50@1.60
Alfalfa seed	.18@20
Mustard, brown	.4½
Millet	.2¾
Flaxseed	.5@5½
Broom corn seed, ton	.23.50

Feed Stuff.

Bran, ton	.29.00@30.00
Feed cornmeal, ton	.34.00@35.00
Cracked corn	.34.00@35.00
Ground barley, ton	.23.00@24.00
Rolled oats, ton	.29.00@31.00

Middlings	34.00@36.50
Oil cake, ton	40.00@41.50
Cocoanut cake, ton	24.50@25.50
Mixed feed, ton	25.00@27.00
Shorts	29.00@31.00

Citrus Fruit Market

LOS ANGELES, Jan. 4, 1911.

The intense cold prevailing generally over the East has prevented the opening of cars, and consequently a very slow market is greeting the fruit now going forward. Before this condition was realized, the heavier shipments of the first of the year had been started, and it is possible that a very quiet situation will be the result. So far as sales are being made, there is no great slump manifested, and it is hoped lighter shipments, together with bettering weather conditions, will combine to clear the market.

Lemons are quiet, with prices favoring Californias, but all grades of fruit are inactive.

Shipments.

Shipments of oranges from Southern California to date from November 1, 1910, 3,254 cars, of lemons 712, or a total of citrus fruits of 3,966. To same date last season, 1,330 cars of oranges, 604 lemons, with total of 1,934 citrus fruits.

Tulare county shipments aggregate about 2,500 cars, Butte county about 400, Sacramento-Placer 135 cars.

NEW YORK, Friday, Dec. 30.—Eight cars of navels and one car of lemons were sold. The market was higher on navels, unchanged on lemons.

COMBINED GRAIN AND FERTILIZER DRILL.

Disc drills have advantages which compel their consideration on the part of farmer and fruit grower. For fertilizer drilling in orchard the Richmond five-disc steel frame fertilizer and grain drill, manufactured by the Wayne Works and sold in California by the Western Implement Co., 131-133 North Los Angeles Street, Los Angeles, is one of the very best. The fertilizer attachment on this machine is made with beveled edge discs, thus obviating the trouble of discs cementing on the edges in bad fertilizer when the machine is in operation. These drills have the strongest chilled iron boot bearings of any machine made. It is fitted with our justly celebrated small rotating cleaning disc, which holds the ground open and the grain is deposited properly. No trash in wet weather can ever catch in this cleaning disc and carry the grain, dropping it in bunches. This feature is an especially patented one, and does the work better than any other device.

Illustration and descriptive matter of this drill may be had by writing the above address.

SUBURBAN HOME.

The general sales agency of the West Riverside Estate (Inc.), has just issued a new booklet entitled "Showing How $2700 Will Grow to $15,000 in Eight Years." It is descriptive of the lands and groves of the company, and is issued primarily in the interest of the property of the Estate. The little book contains much valuable information about the California orange industry and might well be used as a hand book by anyone contemplating an investment in citrus property.

The West Riverside Estate, comprising some 3500 acres of land, is located on the main line of the Salt Lake R. R., five miles west of Riverside. 625 acres are at present in orchard, balance unplanted.

The present company secured the Estate in September, 1910—placed the groves on sale October 1st, but did not get the selling campaign under way before November. In less than two months the sales—made largely to professional Southern California orange growers—total over $200,000, a splendid endorsement in itself.

Owing to the unusual charm of the property, location, etc., the West Riverside Estate is destined in the very near future to be one of the fashionable high-priced suburban home settlements peculiar to California.

A QUEEN.

"Quality, durability, hatchability" is the slogan of the Queen Incubator Co. of Lincoln, Nebraska, which has just issued a "Poultry Guide and Catalog of Queens." The frontispiece is a photograph of Mr. P. M. Wickstrum, under which he states: "I personally back every statement I make about Queen Incubators and Brooders, and guarantee them to be just as represented in this catalog and to do the work I claim for them." The pages following are filled with illustrations of Queen Incubators and their various parts, and give information on incubation and handling of poultry. It's well worth the asking, which is its price.

SELF-SHARPENING SHEARS.

Dull shears are a constant annoyance to the housewife. By a patented device shown on page 31 of this issue shears are kept constantly sharp and in good working order. Every woman should have a pair. They will save their cost several times over each week by enabling you to do more and better work than with the old style shears, which are constantly in need of sharpening and tightening.

(Continued from Page 20.)

lower grades and a great deal of waste in the woods and at the mill. From the standpoint of conservation, the condition would not be so serious if the forests were being replaced after cutting. But the conditions which lead to waste in utilization prevent, also, the practice of forestry. There is, then, a double loss—waste of the present resources and prevention of the production of new resources.

I doubt if this situation can be met at once or by the application of any one remedy. It is clear to my mind, however, that in this case, as in other conservation problems, there must be some present public investment for the future welfare of the country. This investment will take two forms: first, an increased price of products which must approach the cost of producing these by growth, and, second, direct investment in public forests and forestry. So far, the public has not [illegible] condition. There [illegible] the administration [illegible] ests, but the various states are now making the investments necessary to solve their local problems of forestry; the general public is apparently not yet prepared to pay more for the products in order to cover the cost of conservation. One of the first necessary steps is public education regarding our resources and the conditions of their utilization. A better appreciation by the public of the conditions of forest production, logging, and manufacturing of lumber is essential to work out this phase of conservation and bring about a proper adjustment between the limited resources and the needs of the people.

I have felt justified in calling attention to this problem because it is very closely related to the work of forest products and the application of the investigations in this branch of the Service.

As I have only recently become connected with the Forest Service, I feel that I can speak without reserve in praise of the work which has been undertaken. I wish especially to compliment the work of Mr. Hall, Mr. Cline, and their associates in their work of forest products. I wish at this time to express my deep appreciation of the support and cordial co-operation of President Van Hise, and other authorities of the university who have made possible the Forest Products Laboratory.

I regard the co-operation with the university of the greatest value. It is not only in the general educational work in forestry that the Forest Service will be greatly aided, but the association with the university will be very valuable in the conduct of the scientific work at the laboratory. We wish to maintain among our workers that spirit of search after truth which characterizes this great institution. The science of forestry is still in the creative stage. A great deal of the research and of the work of establishing the practice of forestry must be done by the government. To carry on this work, I consider it of the greatest importance that there be no lessening of that spirit of individual initiative, personal responsibility, and high ideals which has characterized the members of the Service under the inspiration of Gifford Pinchot.—Henry S. Graves, Forester of U. S., in address at Madison.

Orange groves at Lindsay, Tulare county, have brought a return to the growers of about $200 per acre.

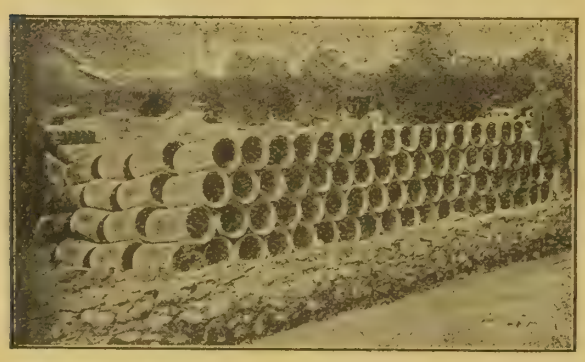
The Luitwieler Non-Pulsating Pumping System

Deep Well Pump Talk Continued :

Cut showing the Luitwieler heart-shaped cam and the only reciprocating pumping mechanism applying the power uniformly throughout the full stroke and uniform speed of the water pistons in both directions. The cam principle is universally conceded to be the most perfect mechanism for lifting water from deep wells or against pressure. Luitwieler pumps are the result of 33 years experience and embody the perfection of the cam principle.

The mechanism is balanced, and our pumps are tested for smoothness of operation, to be run being driven by only a ⅜-inch belt lace, a test impossible with any other reciprocating pump. Luitwieler pumps are in a class by themselves, with fewest working parts and giving most perfect results.

Luitwieler Pumping Engine Co. Los Angeles



THE KT MOULDS

are the result of years of actual experience in the manufacture of concrete pipe or tile These moulds are the strongest on the market and the locks are so simple and easily operated that four men are able to make 560 feet of 10 in. pipe in 9 hrs. You cannot get such results from any other moulds on the market. Complete instructions for making pipe furnished free with order. These moulds are fully guaranteed. We also manufacture a complete line of irrigation appliances. Write for our "Brown Book."

Alligator Pear: The Coming Commercial Tropical Fruit

A Beautiful Tree, producing a Valuable Fruit. Its Cultivation should be Extended. Highly esteemed in West Indies, and will be in California.

GROUP OF ALLIGATOR PEARS, 11 VARIETIES, WEIGHING 23 POUNDS.

A Promising Tree Fruit

No one fruit of a tropical nature has commanded wider attention of late years from plant experimenters than the Alligator Pear (Persea gratissima) of Mexico. And well it may, for not only has the fruit a culinary value, but the tree itself is a noble spreading evergreen. According to Van Mueller's "Select Extra Tropical Plants" the tree is adverse to drouth, hence likes a somewhat humid soil, and is mentioned as available for mild localities outside the tropics. In Jamaica it is cultivated up to 4000 feet; in Eastern Australia it matures fruit outside the tropics. The fruits are generally sliced for salads, and are of a delicious flavor. According to Dr. Froehling, the seeds also possess a medicinal value. As supplemental to what is here said, we refer the reader to descriptive article on another page, by Mr. Will D. Stephens, who is sanguine of its future, and is about to introduce something like a dozen named varieties.

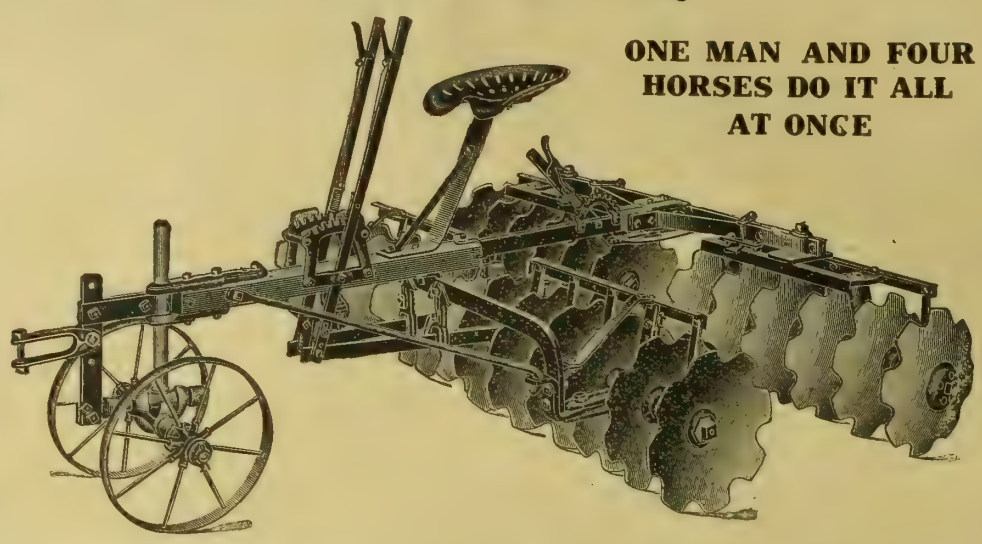
ARNOTT DOUBLE DISC HARROW

A Plow—A Disc—A Pulverizer—A Smoothing Harrow all in one

The SENSATION of the Day

Compare it Point for Point With Any Disc Harrow Made

Double Gangs
Double Cut
Double Throw
Double Levers



ONE MAN AND FOUR HORSES DO IT ALL AT ONCE

The flexibility of the **Arnott "Double-Cut"** in contrast with the stiff action of other two-way harrows is what is making it so popular. This flexibility is possible because of our Universal Joint connecting the front and rear gangs. For lack of this feature other double harrows have a good deal of side draft and will not make a square turn without digging a great hole. This can't happen on the **Arnott.** Independent front and rear levers within easy reach of rider.

Complete description mailed upon application. Write for prices

California Cultivator

Vol. XXXVI. No. 2. LOS ANGELES: THURSDAY, JANUARY 12, 1911 One Dollar the Year

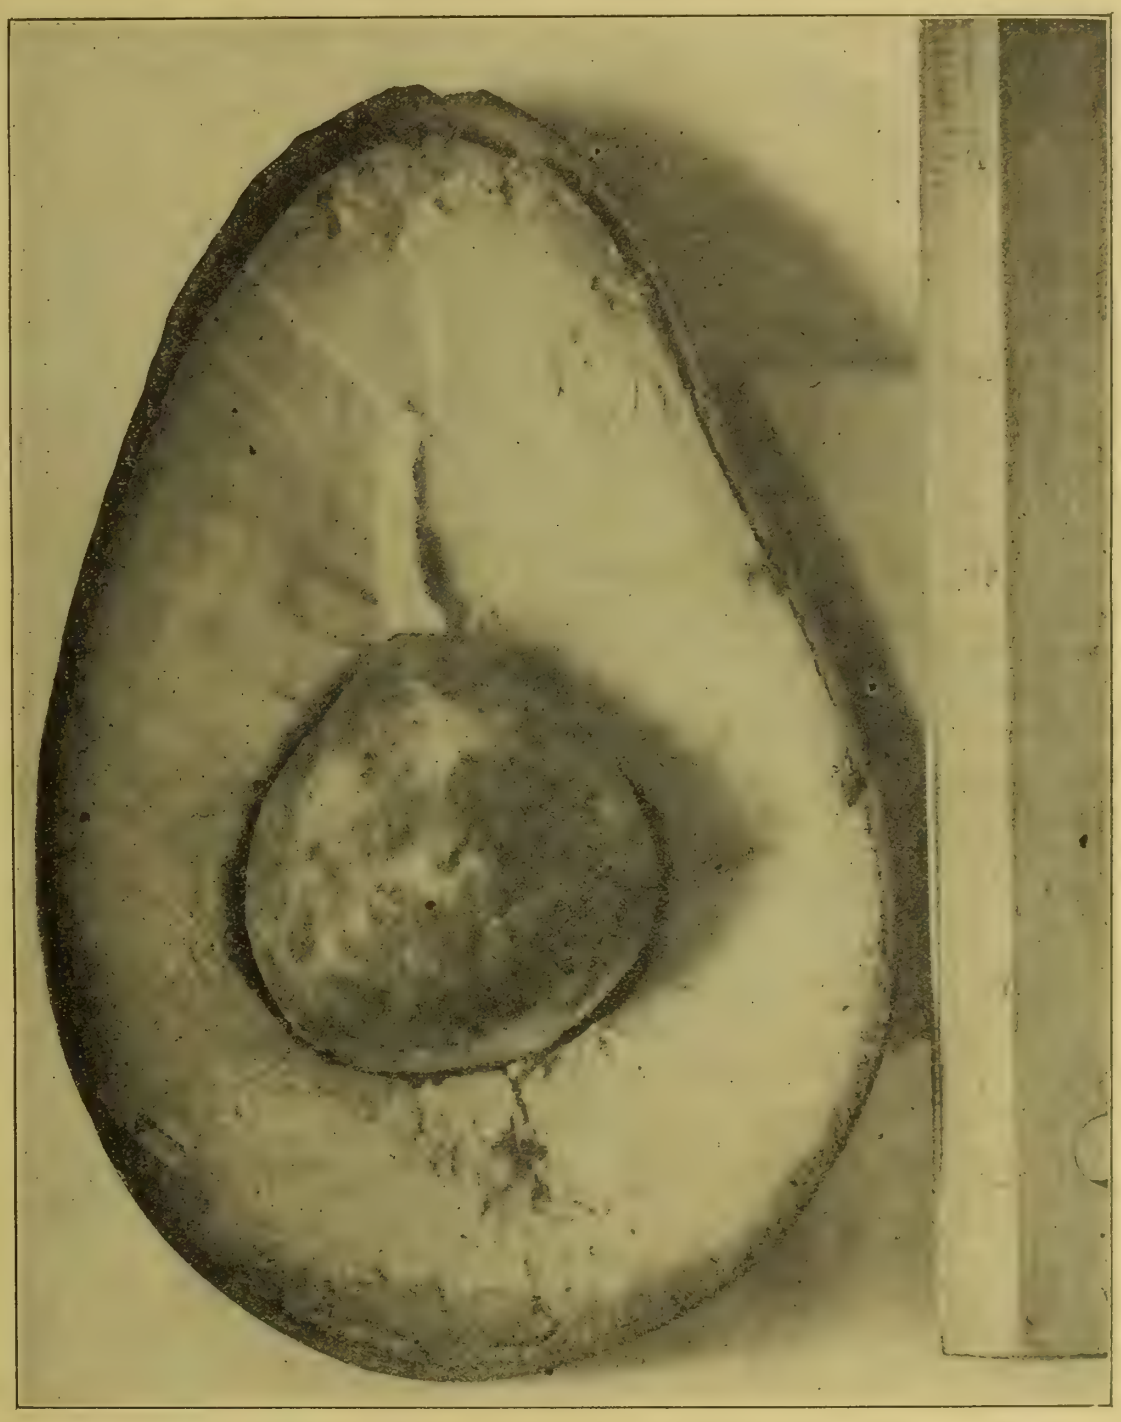
Promise of Enlarged Horticultural Possibilities

Wm. D. Stephens Gives Valuable Information in the Following Description of Avocados, which have Done Exceptionally Well in Some Sections of California

The fruit shown in this issue of the Cultivator and commonly called Alligator Pear, and designated in the U. S. horticultural reports as Avocado, is known in all Spanish speaking countries as the Aguacate (pronounced Ah-wah-cah-te).

The only portion of the United States where they have been successfully grown, so far as the writer has knowledge, are the Indian river section in Florida and our own Southern California. It has been the popular belief that they require a practically frostless climate in order to thrive and produce fruit in commercial quantity. In fact, trees grown here from seed imported from Hawaii and the lowlands of Mexico do not appear to stand any material frosts. On the other hand the tree and fruit are found in their highest state of vigor, productiveness and excellence of quality in the higher altitudes of Mexico where the temperature falls to a point lower than is here believed safe for the growing of citrus fruits, and even where snow usually falls each year. The few trees in California that have reached a producing age and which were grown from seed brought from the high lands in Mexico, have proven that they are at least as hardy and capable of resisting frost as the orange tree.

The Alligator Pear has more the flavor of a vegetable than a fruit with a heavy oily meat devoid of grain or fiber, pale yellow in color and of a delicious nutty flavor. In color and consistency the meat is not unlike butter and in fact is often termed vegetable butter and eaten in similar way by seasoning with salt and spreading upon bread. It is known to be a very wholesome and nutritious food and nine out of every ten persons tasting become devotedly attached to it if they have the opportunity and a purse that can stand the price they bring in our markets. The writer spent some years in Mexico and is now growing these trees in nursery and orchard in Los Angeles county, and also at Jasmin in the early orange belt in the San Joaquin valley. The fruit shown in the accompanying cuts comes from the mountainous district in the state of Puebla, Mexico, at an altitude of more than 6000 feet, a section noted as producing the finest aguacates in the Republic. The writer has visited many portions of Mexico where they flourish, but has found none that approach in size, flavor or shipping qualities these Puebla varieties. The writer confidently predicts as great if not an even greater commercial future for this industry in the citrus producing sections of Southern California than that of orange growing. The profits realized by the owners of the few trees now bearing here are simply amazing, one tree having produced the present year at least $250 worth of fruit at wholesale prices, and other trees much more than $100 each. The fruit from these local trees it should also be remembered is of small size and ordinary quality, weighing from about one-quarter to one-half pound each. The fifteen fruits shown in grouped picture weighed 23 pounds, the largest one weighing two pounds two ounces and the smallest one pound. The tree producing the two-pound fruit is 80 years old and bears 1500 fruits each year, weighing from one and one-quarter to two and one-quarter pounds. Another fine one shown in single picture is from tree only six years old, bearing 500 fruits weighing about one and one-quarter pounds average. Eleven varieties are shown in the group, all very choice and from all of which the writer is receiving supplies of wood for use in budding the seedling stock in his nurseries. There are numerous aguacate enthusiasts in California who will endorse the writer's optimistic views as to the great future in store for this new tree food industry.



A HIGH QUALITY SEEDLING AVOCADO, NATURAL SIZE. WEIGHT 2 LBS., WITH PERFECT FLESH.

The period of ripening of this fruit by proper selection of varieties may be extended over the twelve months. The better known varieties ripen from October to January, but some others have been found which ripen during the spring and early summer months. With care in picking, the fruit is good for thirty days after taken from the tree. This, together with icing and care in shipping will greatly extend the markets and make profitable great production. Of course it is to be expected that the prices quoted in the Cultivator market columns during the last few months cannot obtain when the fruit is produced in a large way, for if such returns could be secured the profits would be fabulous, but with cultivation put upon the basis of that of citrus fruits, a far lower price would be most profitable. With the extension of markets and the introduction of new varieties which lengthen the season, we do not believe there will be any danger of overproduction. One serious drawback has been the difficulty of propagation of some of the varieties, but improved budding methods have been developed and budders now claim that a percentage of buds may be grown equal to those grown in citrus tree budding. The fruit is now being experimentally planted in

(Continued on Page 38.)

These Two Spring Style Books Are Yours Free

Spring Styles are greatly changed—are radically new and most delightful. Never has style news been so interesting, fashions so pleasing, and never have such fascinating Style Books been published as these two reserved for You.

One Book is now ready—the "NATIONAL'S" Advance Sale of New Spring Styles." This Book we want to send you Free by return mail.

Copyright, 1910, National Cloak & Suit Company

The Second Book is the wonder of the Fashion World—the great "NATIONAL" Style Book—224 pages filled with beautiful fashion plates of "NATIONAL" garments offered at money-saving prices. This book, also yours free, will be sent you about January 27th.

Now here is your part. We very much want you to have these Books. We have reserved them for you, but—we need your name and address. So just now send us your request for these Style Books. One will come to you by return mail—the other about January 27th. **Both will be sent *you* free.**

A $2.00 All-Over Embroidery Waist of Fine Quality $1.00

Expressage Prepaid by Us

This is a "NATIONAL" opportunity—an offer of a $2.00 waist for $1.00. And we mean exactly that—without one penny's exaggeration.

No. C613 —This beautiful, new design is made of imported all-over Swiss Embroidery of fine quality. The waist is entirely made of the embroidery—front, sleeves, back and all. The front is made with the new points of insertion trimmed with a very full edging of fine Val and crochet balls. It has the new Parisian straight cut long sleeves, with French band cuffs trimmed with small, flat pearl buttons. This waist will launder easily and beautifully, will wear well, and is extremely stylish and becoming.

Special friend-making price $1.00
Expressage prepaid by us.

Just put a one dollar billin an envelope, give us your size, and get this two dollar "NATIONAL" bargain. If you are not delighted with it we will refund your money upon request. Be sure to state the size desired.

And don't forget to write for your Style Books.

Citrus and Tropical Fruits

SPRAYING FOR THE CITRUS MEALY BUG.

By E. O. Essig, Horticultural Commissioner of Ventura County.

From time to time articles have appeared with reference to handling the citrus mealy bug by fumigation and parasites. Fumigation was certainly given an excellent test in this county, and while, through persistent endeavor, it has accomplished much good, yet to the average orchardist this method is beyond reach. The best work was done in a ten-acre lemon orchard belonging to the Teague-McKevett Co. just east of Santa Paula. Adjoining the old ten-acre orchard, this company planted some 240 acres of young lemon trees, and when the mealy bug was found to exist in the old orchard, the owners sought to exterminate it at any cost to prevent its spreading into the young grove. Former County Commissioner P. E. Smith started this work during the fall of 1908 and it had been carried on until the present time. The first tree-to-tree inspection showed 200 trees infested with mealy bug. After this inspection the entire orchard was fumigated, the dose used being in accordance with Woglum's Dosage Schedule No. 1. A second inspection some two months later showed 75 trees still infested and all these trees as well as those adjacent to them were fumigated as at first.

The third inspection, not being so careful, showed only a few trees infested and these were fumigated with a dosage double that used in Dosage Schedule No. 1. The results of this fumigation looked very favorable.

Three months later a very thorough inspection was made, the time required for the ten acres being six weeks. This inspection showed over 100 trees infested, some of them with eggs only, while others apparently supported only a single individual. The fourth fumigation was carried on differently from any work recorded on the mealy bug. Instead of a double dose being given at once, as was used in the third fumigation, a single dose was given as is the usual custom. After one hour exposure this dose was repeated, thus making the dosage double that outlined in Woglum's Dosage Schedule No. 1 and the exposure two hours. It was believed that this would surely get all of the insects which the one hour exposure and one dose did not kill. The results were indeed very satisfactory. So much so that the fifth inspection, which was even more careful than the fourth, revealed only four trees slightly infested. These trees were fumigated with the same system of dosage as soon as they were found by the inspector. A later inspection has revealed no mealy bugs, but only after some time, yet, can we make sure of this. The work shows that the reduction of the pest is exceedingly great and through repeated fumigations the pest can be practically exterminated in an orchard, which was badly infested in all parts. To demonstrate this the double dosage and double exposure system was carried into a very badly infected orchard. The results were little better than what was obtained by a single dose and one hour exposure. In many cases only about 50 per cent of the female bugs were killed, while the percentage of the eggs remained unknown. The cost of the single time for an average lemon tree, including labor and tents, was nearly $1.50.

Believing in a three-hour exposure and a triple dosage, an owner of a badly infested orchard, wished his orchard so treated. After two nights' work a halt was called to await an inspection so as to get some idea of the results obtained. An inspection followed which showed as many as 40 individual mealy bugs on a single tree. The work was stopped and a closer inspection made which resulted in the work being dropped. The cost per tree was near $2.25 and the results very poor.

* * * *

Other fumigation efforts are chronicled by Mr. Essig, in one of which the average cost per tree was $2.25. This is prohibitive in general practice. He afterward concluded:

* * * *

It was after this and other work that my attention was turned to some other means of combating the mealy bug, than by fumigation or the use of the already promising parasites which were working very slowly. To sprays I turned first, believing that a mixture could be found which would do the work. Sprays seemed advisable for the following reasons:

1. At most times of the year the mealy bugs are scattered over the tree in the most exposed manner. Only during the winter months are they massed and more or less protected by their numbers.

2. The only protection afforded to these soft-bodied insects is a thin, white, waxy covering. The requisite for a successful spray would be the power of penetrating and dissolving this waxy coat.

3. A spray which would kill the adults would exterminate all the eggs on the tree at the time of spraying.

4. Weather conditions are more favorable for spraying in this country than for fumigation, because of damp nights, east winds, etc.

With these things in mind, work was begun with both wet and dry sprays. The section chosen was an average-aged lemon orchard very badly infested with mealy bug—a section of about two acres, and where parasites had not been introduced.

The work was carried on during the months of January, February and March, when the trees were more or less dormant, and when the mealy bugs and eggs were massed in great clusters on the trunks, limbs, leaves, and fruit of the trees. The results were so good that beginning July 1st, over 100 acres will be sprayed and steps taken to make a general cleaning up of the entire mealy bug district. Of course there are many things yet to be perfected in regard to the time of spraying and the manner of application, but with an efficient spray to work with, these details will develop only with experience and time.

* * * *

Many sprays are then described and the results of their application given, after which Mr. Essig decided that the carbolic acid emulsion was the only practical one, regarding which he says:

* * * *

Carbolic Acid Emulsion.

The most satisfactory of all the

sprays used in combating the citrus mealy bug is the Carbolic Acid Emulsion. This is probably due to its penetrating qualities which enables it to dissolve the waxy covering of the mealy bug and to come in contact with the naked body.

The formula for mixing up this spray is as follows:

Crude Carbolic Acid..... 5 gals.
Whole Oil Soap.....40 lbs.
Water (hot) .....40 gals.

The 40 gallons of water are first poured into the cooking kettle and allowed to boil. While the water is getting hot, the whale oil soap is cut into fine pieces, so as to make it dissolve easily, and added to the water. When the soap is all dissolved in the hot water, the carbolic acid is added, and all is allowed to boil for a short time to insure thorough mixing. The whole operation requires less than one hour. The contents make about 43 gallons of rich stock solution. For spraying, the stock solution is diluted one to twenty of water, thus making approximately 860 gallons of spraying material. The stock solution will keep indefinitely, but is preferable fresh. When diluted with water it makes a perfect emulsion and can be applied with any spray pump, since an agitator is not needed. When the stock solution is allowed to stand for some time it is best to stir it up before diluting it for spraying.

The resulting spray is very easily handled, it needs no agitation, no straining, is easily and simply made, does not rot the hose or rust iron pipes, and is perfectly harmless to the eyes and hands of the sprayers.

Applications.

In spraying for insects which are protected by a woolly, cottony, or waxy covering, it is essential that an adequate force behind the spray be employed. In the case of the mealy bug it is absolutely necessary to have a power spray pump. This will enable the sprayer to develop the power necessary. In our work the least pressure used was 100 pounds and the most satisfactory pressure 250 pounds. A three nozzled spray seemed to give the best results, for a thorough drenching could be given any spot instantly, and the top of the tree could be more effectively reached. With such a spray there is little danger of missing any considerable surface of the tree, a thing to be guarded against, for every spot untouched means not a few mealy bugs left alive on the tree for the next year. This can be avoided only by thorough work and regular applications. If a few insects are left in a secluded place it will not be long before the young are born and the adults die, or the adults themselves, may move to a more favorable place. The young always move away from the parent and often rove extensively after hatching. The life cycle is quite long, lasting six to nine months, so three applications of spray within this time will surely eliminate most of them. In a badly infested orchard an application should be made once every two months until the conditions are made much better.

In the experimental and field work where the trees were normal in size, and badly infested with eggs, larvae, and adult mealy bugs, 15 gallons were given to each tree, at an application.

Cost of Spraying.

In large quantities the cost of materials is as follows:

Crude Carbolic Acid.....25c per gal.
Whale Oil Soap.....6½c per lb.

A mixture of 43 gallons of stock solution according to the above formula would cost $3.85. This stock solution makes 860 gallons of spraying material less than ½c per gallon. Using 15 gallons per tree this would make the cost near 7c a tree for a single application. After the first two sprayings it would not be necessary to give such a large dose, which would cut down the expenses somewhat. The labor would probably cost less than the cost of chemicals per tree.

Comparing spraying with fumigation, every argument of expense is with the former, and the results are certainly greater in proportion to the cost for each application and as many applications are necessary for fumigation as are for spraying at a cost of about five times as much every time.

Time for Spraying.

In a badly infested orchard the work should be taken up as soon as possible so as to eliminate all of the insects exposed. After two or three successive sprayings within six or seven weeks, a regular system should be followed, just as we fumigate regularly for black scale.

In the late fall, during the months of October, November, December, and on into January, the mealy bug and their eggs are massed in great numbers all over the tree and fruit. Spraying during these months is somewhat difficult, but these are the advantages:

1. Nearly all of the eggs which would produce new broods for the coming year would be destroyed. While the young continue to hatch throughout the entire year, there is a period in the spring when the egg masses, which were deposited in the fall, hatch and the young come forth in great numbers just in time to attack young growth. Therefore spraying in the winter is very effective in preventing these spring broods.

2. In the winter the lemon tree has its minimum amount of foliage, the tree is more open and offers greater opportunities for effective spraying, especially in respect to the large limbs, upon which are massed the most of the eggs.

3. In the winter months the tree will stand more than in the spring months. This was demonstrated by the Lime-Sulfur spray, which killed the new spring growth and did no injury at all to the tough, leathery growth of the winter. The hot weather in the summer is injurious to a sprayed tree. It has been proven that a tree cannot stand near as strong a mixture of distillate and water in the summer time as it can in the winter. This is true to a great degree with regard to any spray.

As was pointed out above, the young begin to appear in great numbers as soon as the new growth starts. These young insects seek first the tender growth and the young fruit buds. Upon the former they settle indiscriminately while on the latter they settle just around the base of the young fruit. I have counted as many as 150 individuals around a single young lemon.

At this period all infested trees should be given a liberal application, in order to preserve the new growth and setting lemons; the greater number of the latter will soon drop unless the pests are removed. In case the fruit matures, the mealy bugs develop with it until, when it is ready to pick, it is so scarred as to be fit only for third grade when it might have been first. While the carbolic acid emulsion did spot the younger, reddish growth, no material change was done at this period, which should prevent spraying. Later in summer, after the young growth hardens a little, is a

LARGEST CITRUS NURSERIES IN THE WORLD

Parties contemplating the planting of citrus groves this coming spring will do well to send for our prices soon, as there will evidently be a shortage of strictly first class stock. Write today for particulars, or, better still, pay us a visit so that we may be able to show you just what we have.

more favorable time to spray, except that the foliage is very dense and thorough work difficult.

* * * *

The disastrous effect of the mealy bug on the navel orange on which it works from the navel and often into the center of the orange is described. "In a single navel thousands of eggs are deposited." This makes all the fruit unfit for use. Valencias and lemons are worst affected at stem or

A MAGNIFICENT SPECIMEN; WEIGHT 22 OUNCES.

where fruit lies together. As to number of applications of the spray, Mr. Essig says:

* * * *

Number of Applications.

As every sprayer knows, it is impossible to reach all parts of a tree at a single spraying. In combating

ANOTHER VARIETY; WEIGHT 1½ LBS., BUT OF HIGH QUALITY.

so serious a pest as the mealy bug it is therefore necessary to make a number of applications to get results.

In a badly infested orchard three sprayings should be made within two or three months. The orchard will then be freed from serious smutting and the fruit will be hardly scarred. But the work must not be stopped. The mealy bug is a pest which can hardly be eradicated, for it has too many host plants. Parasites are going to do good work as soon as they get started, but the man who wishes to keep this pest down can do so by first cleaning up the orchard as stated and then spray once or twice a year with the carbolic acid emulsion. The main thing is to keep fighting. That is the only way to get rid of any kind of infection, whether it be weeds, fungous or insect pests.

* * * *

The work of parasites is encouraged, but in isolated sections until their worth is proven. The effect of the carbolic spray on the smut fungus was found beneficial for fruit from sprayed trees cleaned perfectly in the washer. Such fruit also showed a lower percentage of culls.

The summary is as follows:

It was estimated that the benefits derived from the spray in cleaning the fruit alone, paid for the cost of spraying. The carbolic acid emulsion gave the best results in this work.

Fruit which was very dirty from smut of black scale was washed in a weak solution of the carbolic acid emulsion in the packing house washer with very good results. The kerosene, which had been used, benefited only the lemons floating on the top of the water, while the emulsion benefited all alike. The mixture was as follows:

Five gallons of the stock solution was added to 200 gallons in the washer. This amount ran one-half a day—steady washing. Only in cases of very dirty fruit has this given any very great advantages over other washing materials.

Carbolic Acid Emulsion and Black Scale.

Many fruit growers here believe that any spray which will kill the mealy bug will certainly slaughter the black scale, but such is not the case. The black scale, even when quite young, is not so susceptible to this spray as is the mealy bug, due to its hard coating. The black scale is protected by its hard shell which is not much damaged by this spray, while the mealy bug is protected by a cottony wax, which is readily dissolved by it. Therefore this spray is not recommended for black scale, although it may kill a great many of the young insects.

Practical Suggestions.

1. Use every means to get rid of the citrus mealy bug at any cost.
2. Spray as soon as you can, and as often as necessary.
3. Use fresh and good material.
4. Do not think that because you do not kill all the pests at one spraying that the spray is not good. Remember that this is a very difficult pest to combat.
5. Use a power pump.

Pressure.

Great difficulty was found in keeping a high and constant pressure with run-down spray pumps. This work is very particular and the pump must be overhauled at the beginning of the spraying season so that the best possible results may be obtained. The pressure should never be less than 200 pounds. In many cases where it went as low as 100 pounds or even 140 pounds the results were not satisfactory. The high pressure not only penetrates the cottony protection better, but it whirls the leaves and enables the sprayer to hit every part of the tree. Much of the poor results obtained were usually traced right back to this cause, which though a small thing, is extremely important in spraying for the mealy bug.

Application.

There is always fault found with the application of sprays. Either the sprayers are careless or, as found in some cases here, did not wish to do the work, so pushed it as rapidly as possible, giving each tree only half the required dosage. By careful work we found that if applied rightly, the Carbolic Acid Emulsion did excellent work, so if you get poor results look up this matter. Few men enjoy spraying and farm hands like to see it finished as soon as possible. Sometimes it was necessary to go over the work twice in order to get beneficial results at all, and in those cases we found that the first dosage given was less than half what the sprayers were instructed to use. Careless spraying is useless.

Material.

The commercial materials used must be carefully examined, for we have found some unfit for anything.

As a rule the crude carbolic acid was good, but if it is allowed to stand in wooden barrels in the hot sun for any length of time it is liable to evaporate and escape, leaving a concentrated liquid which is disastrous to the spraying apparatus because it collects in the hose and stops up the nozzles, and to the trees because it may drop the leaves.

With the whale soap we found considerable trouble. In all we have handled some three tons and find two distinct grades. One is a light brown and is good, while the other is very dark—nearly black—and is worthless. Out of the last ton some 400 pounds were set aside and will be shipped back to the factory. The trouble with this poor grade seems to lie in that it will not form an emulsion, no matter how much is used. Several tanks were sprayed out before the mixer was aware of the difference, which showed up immediately on the trees. No harm was done to the foliage or to the mealy bugs. Therefore in view of this experience you are advised to avoid dark whale oil soap. It is not good.

General Results.

At times the work proves very encouraging, while again it does not show up well, but I am satisfied that all poor work lies with the above named faults. Spraying citrus trees for anything is difficult, and doubly so when spraying for the mealy bug. The pest is bad and hard to kill. Remember it cannot be killed with reckless spraying. Good work always shows up in the results. Remember this in your spraying work.

HORTICULTURAL TRAINING FOR BOYS.

By E. R. Ong, San Jose.

We have heard so much of the corn-growing contests and others of a similar nature in the East, whereby the boys and girls are being trained each in their respective lines. But how little scientific training the boys of California receive, who are doing so much of the work of the orchards and vineyards. Often the fathers do not take the trouble to explain to their boys the principles which underlie the work. And as yet the schools which give adequate instruction in these lines are so scarce that it is only the favored few who can avail themselves of these privileges. But when it comes to the most common work, such as can be entrusted to the most ignorant workman, then he generally has his full share, even when there may be ample means for hiring such work done.

It has been said that a boy's definition of a farm is "A place to work all day in the field and do chores half the night." And what else can we expect, when he works blindly along without any understanding of the work he is doing?

It is true that instruction in public schools on these lines is very limited, but we have good, live papers at a moderate cost, which will go a long way toward keeping one abreast of the times. A few high-grade books, treating especially on California conditions, and, besides these, there are the United States and state bulletins, which are sent free to everyone who wishes for them. These take up every phase of orchard work, including fruit packing, spraying, grafting and cultural operations.

Teach him of the different roots on which our nursery stock is grown, their effect on the stock, the soils to which they are adapted, and those that may be used locally. This will lead naturally to an interest in the different ways of propagating in the nursery and root and bench grafting, which everyone who expects to be an orchardist should know something about. And a knowledge of the principles and skill required in the work would give an added charm to the orchard such as nothing else would do.

A pamphlet sent free by the United States Department of Agriculture, Washington, D. C., entitled "Top Working of Orchard Trees," will give sufficient information so that any bright boy can take up the simpler forms of budding and grafting. Begin on an apple or pear, as they are more easily worked than some others, and graft a number of varieties on one tree. Instead of grubbing out the unprofitable trees, try working them over with buds or scions cut from a carefully selected tree which has some desirable feature, such as regularity of bearing or freedom from disease, which we desire in our orchards.

No two trees are just alike, and if an orchard is carefully watched for two or three years a few trees will be found which bear more regularly, and perhaps a larger crop, than those around them. These are the ones from which to get buds and scions, and they should be taken from bearing wood rather than from suckers or young trees that have not begun to bear. This opens a wide field, and comparison and selection will probably extend to neighboring orchards and to co-operation with the nurserymen. By so doing you are not only making your own orchard more profitable, but you are assisting in the greatest work of horticulture, that of making more valuable the plants and trees that have come under our care.

AN IOWA PLANT BREEDER.

The fundamental problem of mankind is to produce food for itself. This food must grow out of the earth and in the sea. In the last analysis, it all depends on the vegetable cover of the earth. How to make the vegetable kingdom more productive to the needs of man is therefore a problem that concerns all persons who at any time live in the world.

Great and serious study has been given to this foundamental problem in the last century, and the problem must increase in importance as every new generation adds to the population of the earth. We are eradicating pestilence and insanitation, and are beginning to think of putting an end to war; all this should allow the human race to increase rapidly in the future. But the future increase will probably depend more on social and economic factors than on physical factors alone, and the foremost economic factor is the facility or the difficulty with which the race may be fed.

The plant-breeders are of two groups, those who are not connected with an organization, but who prosecute their work on their own resources, usually in connection with a nursery or seed business, and those who are attached to some college, experiment station, or government department.

As an unattached plant-breeder, Mr. Charles G. Patten of Charles City, Iowa, should be mentioned, both because his work is deserving and because it is of such long standing that I can write of results actually accomplished.

Mr. Patten was a farm-boy in northern New York, reared in the general mixed husbandry of that region. At an early age he went to Wisconsin, where, being impressed with the need of apples specially adapted to the climate, he began to raise seedlings. In 1864 he removed to Charles City, and settled on the raw prairie near the town; in 1866 he established a nursery business. As he attempted to supply the needs of the new and untried region, he found himself compelled to test great numbers of varieties of fruits and ornamental plants from the older country, and also to attempt to breed new ones that might more perfectly meet the conditions of very cold winters with dry killing winds. The result has been the production of the Patten Greening, now a standard apple of the northern Iowa-Wisconsin-Minnesota region (or what may be called the box-elder country) and several other accepted varieties. There are also large numbers of new things yet awaiting fuller tests. It is not often that a man has more than one accepted new variety to his credit.

In the region that I have indicated, the Baldwin, Greening, Northern Spy, and other familiar eastern apples, are

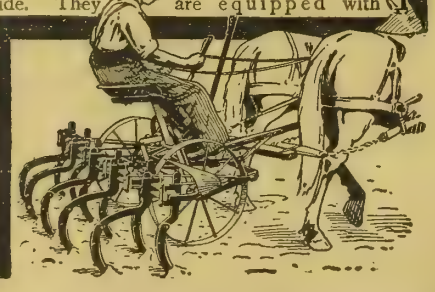
Planet Jr.

No 41 Orchard and Universal Cultivator

Adapted especially for the work of orchardists and vineyardists. Does quicker and more thorough work than any other implement made for fruit-growers' use. Planet Jrs were invented by a practical farmer who felt the need of just such implements. They are backed by over 35 years' manufacturing experience, and are used by thousands of orchardists throughout California and other fruit-growing districts. They furrow, hoe, and cultivate to any required depth, and are made in sizes which work up to 7 ft. 9 in. wide. They are equipped with side-hitch and fruit and tree shield. Can be changed to a disc-cultivator. High-carbon steel frame, steel tongue, low wheels enclosed by the frame. Strong, substantial, easily handled.



We carry stock in San Francisco. Agencies in all principal Pacific Coast cities. Write for name of nearest agent, also illustrated 56-page catalogue of all 1911 Planet Jr implements. Free and postpaid.

MORRIS & SNOW SEED CO. 425 So. Main Street Los Angeles, Cal.

killed by the winters. Mr. Patten observed that trees and shrubs which did well even in his Wisconsin experience were lacking in hardiness in northeastern Iowa. He pondered all these facts, and worked out a theory or plan of procedure. It was clearly necessary to secure a new stock or race of fruits. There are still several theories as to the best way of doing this with apples. One plan is to import varieties of fruits direct from a country of similar climate; the noted introduction of Russian apples thirty or forty years ago was the working out of this idea. Another theory is to improve the wild crab-apple that is native to the region. From this crab, probably hybridized with the domestic apple, the Soulard and a few others, have actually been produced; but all are of small value where any other apple can be grown. Another idea is to use the Siberian crab as a foundation from which to breed. Another plan, or, rather, practice, is to plant indiscriminately the seeds of eastern varieties, in the hope that an adaptable form may appear. The Wealthy apple, our leading cold-country variety, was actually produced in this way, Peter M. Gideon, in Minesota, sowing a bushel of apple-seed from Maine, out of which this one seedling proved to be valuable.—From L. H. Bailey's "An Iowa Plant Breeder" in the January Century.

HARVESTING THE FRUIT CROPS.

A movement has started in the prune orchards of the Santa Clara Valley that bears so directly upon educational questions that it is here illustrated and sent out for the consideration of the horticultural people and the school people of other parts of the state. The idea is to enlist the interest and the labor of the children and the people of the villages and the towns in the harvesting of our perishable fruit crops, paying them full market wages for their work, furnishing them safe and attractive camping places, facilitating their coming and going, and giving them a season of healthful, active, outdoor life.

This is a practical course of study in California agriculture that may well command the co-operation of the educational forces of the state. The school term may very well begin and close so that the children and their parents can take part in the chief industry of the neighborhood. The curse of the fruit grower is the lack of labor in the gathering of his crop. This it is that brings indigestible foreigners upon us, Japanese, Hindoos, Chinese. This it is that is forcing much of our richest lands into the hands of aliens. The safety of our nation lies in having our land owned by our own people who earn their living from the soil. It is a splendid thing to see the schools closed and the villages depopulated during the harvest season; to see the mothers and the children living outdoors for a time and helping to pick the hops, gather the grapes, dry the peaches, take care of the prunes, apricots, tomatoes, and all that. It makes stronger, happier, wholesomer people. Everybody may well join in it. There is no loss of dignity in it. It advances the interests of California's great industry, the industry by which we must live for centuries into the future, with the world for a rival. It is truly educational, in the best and highest sense.

Homer A. Craig, a fruit grower at Campbell and president of the Farmers' Union, is the leader in this idea. For four years he has been giving it practical trial in his orchards. He finds that by offering employment to whole families and providing them with decent opportunities to live during the fruit season, he can avoid the use of Asiatic labor. The children old enough to work take part in the industry, and the little ones play about under the watchful eyes of the mothers. All gain health and vigor, cheeks fill out, faces grow tanned and ruddy, and habits of industry, thrift, and independence are formed. Really, this is a patriotic enterprise for all concerned. The alien laborers that we draw in for this temporary purpose do not leave the country when the work is done. They must be reckoned with and supported by the nation for all time to come, even when the work is needed by our own people.—Edward Hyatt, Supt. of Public Instruction.

FIGS IN CALIFORNIA.

The fig is destined to become one of California's most valuable products. Its universal popularity, and its great value as an article of diet, its splendid keeping and carrying qualities; the long life of the trees; their great productivity; their almost entire freedom from pests and their splendid adaptability to California conditions—all these things are factors which must inevitably place this fruit among our most cherished possessions.

Even now a fig orchard in bearing is a valuable property; soon it will be rated among the most "gilt-edged" of investments, if the allied industries of fig-growing, fig-packing and fig-marketing are conducted with a reasonable degree of honesty and foresight. If they are not so conducted, this class of property will not be so "gilt-edged."—Gerald Geraldson.

Children receive 10 cents a quart for the cocoons of the Tussock moth which they collect in the streets and public parks of the city of Buffalo, N. Y.

Home Grounds Beautiful

PLANTING A LAWN AND CARE.

The formation of the lawn is often hastily and imperfectly done. The best time to avoid the bad effects which naturally arise from poor judgment, is at the start. It is well to make several maps and draw a different plan upon each, thus securing the means of making comparisons and choosing the one which combines the greatest number of good points. Too great care can not be taken in making various plans and in finally deciding upon one. The locating of existing objects, such as the dwelling, outhouses, trees that may be standing on the grounds, or the planting of ornamental trees or shrubs, is work requiring forethought.

Grading.

After the plan has been completed, the grading of the surface is the first thing in order. Grading is one of the distinguishing features of a complete lawn. All elevations should be plowed up, and the ground from them should be scraped or hauled into the depressions which may exist. At least eight inches of good soil should overlay the whole in all places; also see that the elevations where the soil was removed be replaced with top-soil to this depth.

Where walks and drives are to come the soil should be excavated to the proper depth for filling in with road material. When this rough grading is completed, drains should be laid wherever necessary. Where the process of grading has involved much filling in, time should be allowed for the settling of the soil; and during this period a hoed crop may be cultivated to advantage.

Preparation.

It must be remembered that the lawn when once formed is to remain undisturbed; hence the importance of the most thorough preparation of the soil. After the ground is shaped to the desired grade, then the whole should be dug or plowed. The soil from the first furrow made in plowing will be thrown above the level; after the piece is overturned this should be drawn or wheeled into the open furrow left by the plow in finishing, that all may become even again.

Before plowing the land it should have a top-dressing of well-decomposed manure, at the rate of say eight or ten cords to the acre. The surface then should be made as fine as possible by repeated harrowings and thorough rolling.

To facilitate the work of tree or shrub planting, which next has to receive attention, small stakes should be set at points marked on the plan; planting should be done carefully and without unnecessary digging of the graded surface. After this the harrow (or, better yet, the rake) may again pass over the surface, and afterward the roller. And then the surface is ready to be sown.

Seeding.

The greatest care should be taken to procure seed of the very best quality. A mixture containing perennial rye grass, Kentucky blue, sweet vernal, extra cleaned red top, and Dutch clover, makes a good mixture. Do not fall into the common error of using seed sparingly. Four bushels to the acre is the proper quantity. The time for seeding is from the middle of April to the middle of May, or from the middle of August to the middle of September, in northern latitudes.

The sowing should be done by hand, the seed scattered evenly over the surface. Select a day when there is little or no wind. A very light raking or brushing, and after that a thorough rolling, is essential.

Sodding.

The edges of all grass-sown lawns bordering on walks, drives, flowerbeds and terraces, should, for protection, be sodded one foot wide. In taking up the sods they should be cut into squares of about one foot wide by five or six feet long,—which can be conveniently rolled up for handling. Cut the sods about an inch and half thick. In putting down the sods they should be laid closely, filling the crevices with good soil and giving a light sprinkling of grass seed, and beating them smoothly with the back of the spade.

Mowing.

The number of times the lawn should be cut will depend very much upon the character of the season. Ordinarily, the lawn is mown every week or ten days. The oftener the lawn is mown and the more frequently it is rolled, the better and finer the turf. During the hot, dry, summer months it is best not to cut the grass so closely as in the spring or fall. The grass, if it is very heavy, should be raked off after each mowing.

Top-Dressing.

Where it is necessary to apply fertilizers after the grass has started in order to maintain fertility, a fall dressing of old and well-decomposed manure should be used. When such can not be obtained, commercial fertilizers may be substituted.

Obstacles To Be Overcome.

The principal things to be overcome in the establishment of a perfect lawn are poor soil, bad drainage, dry weather, inadequate water supply and weeds.

Poor soil and drainage are overcome by thorough preparation and enrichment of the soil. Until the turf is well formed constant attention is necessary to prevent the invasion of weeds. They should be removed upon their first appearance, and in no case allowed to gain a foothold; for when once established their removal becomes very laborious.—Prize Article in Journal.

Soil stirring, cultivation, destruction of weeds, and watering will all give abundant work during this month. It is especially necessary that all vegetable plots should be kept free from weeds. Under close cultivation conditions, weeds greatly retard the growth of other plants.

The surface soil should receive regular and constant cultivation. All clods and rough portions should be well broken up with the hoe; weeds should be kept down rigidly, and this can only be done by frequent stirrings of the surface. If any chemical fertilizers are to be fed to the plants, they should be applied immediately before a cultivation.

The Tule Indian tribe has forwarded a protest to the Department of the Interior against the ruling made by the agent that cattle may be grazed on the reservation by the payment of fifty cents per head.

WINSEL'S GARDEN CALENDAR

FOR THE MONTH OF JANUARY

FRUIT TREES. Deciduous trees are planted to the best advantage in January. Peaches, Plums, Apricots, Almonds, Apples, Pears, Figs, Persimmons, Walnuts, Berry Plants and Grape Vines. Send your orders to 211 South Main Street, or visit our nurseries, S. W. Cor. Washington and Figueroa Streets, Los Angeles, and select your trees. We have a fine assortment, and our trees are extra large. Send for price list.

FIELD GROWN ROSES. Two-year-old. We have a complete assortment of varieties best adapted to Southern California. Price 35c each, $3.50 per dozen. Freight prepaid to any point in Southern California. Send for our Rose List.

VEGETABLE GARDEN. Sow Peas, Beets, Carrots, Cabbage, Lettuce, Parsnips and Radish. Plant Onion Sets, Rhubarb Roots, Cabbage and Cauliflower Plants, Chives, Horseradish, Tarragon and Asparagus Roots. On the Hot Beds, sow Egg Plant, Tomato and Pepper Seeds.

LAWNS. Put in your lawn with our Kentucky Blue Grass and White Clover Seeds. We carry the best grades only.

FLOWER GARDEN. Sow the seeds of Asters, Sweet Peas, Coreopsis, Centaurea, Alyssum, Poppies and Pinks. We have on hand the following plants that can be set out now at 25c per dozen, $1.50 per hundred: Gaillardia, Verbenas, Pansies, Violets, Stocks.

SHEEP MANURE. Free of weeds and odorless. Gives immediate results. Delivered anywhere in Los Angeles, Pasadena or Hollywood for $2.25 per hundred pounds.

LANDSCAPE GARDENING. Estimates and plans furnished.

OUR FREE CATALOG. Giving directions how and when to plant everything. The new 1911 issue will be out in about thirty days. Send in your name NOW for a copy.

Garden and Field Crops

BREEDING PEDIGREED POTATO SEED.

In regard to the much discussed question of what size seed potatoes to plant, how to select the tubers, etc., I have worked out the following, which I think the very best way: First, I select as many of the best tubers of a variety as I wish to raise my next year's seed stock from, or, in case I buy a new variety, I take them all and plant by hand, taking the uncut tubers in a basket, and drop them in the row at the same time; that is, I take a tuber from the basket on my arm, cut and drop as far as it will go, then take another, etc., until I have them all cut and dropped; then cover by hand, making a unit of each tuber. I think this is far better than first cutting and throwing together, and then planting the selected tubers, as that way loses the characteristic or the individuality of each tuber.

What do I find through the growing season and at digging by my way, where each tuber is planted as a unit (together)? I keep close watch of them in the latter part of the growing season, and find the majority of the tubers making a uniform top growth. I am not able to distinguish the hills of one tuber from another, and the same when dug, but I find a few weak-growing tops or degenerates, not single hills here and there, but almost invariably several together, or as many as the original tuber, about six or eight. This plainly shows that the degeneracy of potatoes is in the whole tuber, and not in the single eyes. Of course, these are marked, or dug out before the others are dug, and almost invariably yield small potatoes. I have not found that the size of the tuber planted has anything to do with the degeneracy, provided, of course, they were not taken from degenerate stock, but, planted as a unit, have found that any size tuber is liable to degenerate or produce tops that would blight early and produce small tubers. Why, I cannot say. We can readily see that if a planter selects the small potatoes year after year he is bound to get more and more of the degenerates to reduce his yield, and will then say his potatoes are "running out."

In growing my seed stock in this way, I have discovered at rare intervals tubers that would grow an extra large top, remaining green after the others had died down, and when dug would give a better yield than the rest. I have been testing some of these, and think a new variety can be originated in this way, as well as by planting the seed from the seed balls. Of course, these are sports or variations from the original type. Seed stock planted and treated like this (and there will be nearly always a few degenerates to dig out each year from aparently good tubers) will keep its original vigor indefinitely, but I do not believe that a variety can be much improved over the original, except a sport or variation could be found, and then it would become practically a new variety. To raise one's seed stock this way, it is not necessary to have a separate field; a few rows can be planted by hand by the side of the main field, digging out the inferior or degenerate hills separately, treating them otherwise the same as the main field. When one raises his own planting stock, I believe this extra work will pay grandly. —Charles L. Todd, in Rural New Yorker.

CABBAGE CULTURE.

From an excellent bulletin entitled "The A B C of Truck Growing," by Samuel H. Dixon of the Texas Department of Agriculture, we take the following cultural directions:

It is the custom to make a seed bed about four feet wide, level and about six inches above the surrounding surface. The seed should be sown from one-fourth to one-half an inch deep, according to the character of the soil. Make the drills across the bed from four to five inches apart. The bed should be kept moist and protected from the rays of the sun.

The cabbage is a very gross feeder and requires a fertile soil and good cultivation to reach perfection. Cultivation should follow each rain. In fact, the most successful growers favor weekly cultivation, even in the absence of rain. There is no crop grown that responds more readily to cultivation than cabbage.

The soil best suited to cabbage is a moist, well drained, sandy loam soil. If it is not rich with humus it must be thoroughly fertilized with a nitrogenous fertilizer.

Cabbage ought to be ready for the market in from five to six months from seed planting, depending, of course, upon the weather conditions. To insure the living of the plant, I always puddle the roots thoroughly before planting. This is not a necessary operation, however, if the soil is moist and weather conditions are favorable.

Rows in which the transplanted plant is to be set should be three and a half feet apart. The distance in the row will be governed largely by the variety planted. The larger varieties should be set twenty-four inches apart, while the small varieties can be set from sixteen to eighteen inches apart in the rows.

Cabbage should not be cut until it has formed a compact hard head. It is usually shipped in crates. An acre should produce from 150 to 200 crates.

Of varieties grown in Southern California the Early Winnigstadt easily occupies first place. It is one of the best early cabbages in cultivation. It is certainly deserving of its popularity; grown extensively for market and shipping. Its merits are many, among which are large heads for an early sort, small outside foliage and uniformity of crop; pyramidal in shape; very solid, fine texture and sweet.

The Eureka or First Early is a flat-headed cabbage, fully as early in maturing as the well-known Early Jersey Wakefield. It is a cross of a fine strain of Early Jersey Wakefield on the well-known Succession cabbage, and is now thoroughly fixed as to type. The heads are large and very solid and the leaves tender, being entirely free from coarseness. The plants may be set as close in the field as the Wakefield, and can be depended upon to head up well.

The Farmers Union of Walla Walla, Washington, will maintain a fight at Olympia during the session of the legislature to secure laws more in the interests of the producer.

Live Stock and Dairy

Dairymen and stockmen are requested to write of their experience. Mrs. Sherman is always willing to answer queries and this, with experience of other workers, will make this department of greater value.

UTILIZING THE BY-PRODUCTS.

Address by Dr. James Withycombe at the Dairy Meeting at Eugene, Oregon.

The cow is the great conservator of wealth. We hear much these days relating to the conservation of natural resources. This refers mainly to the forest, minerals and streams. The great problem of conservation, however, which much more largely influences the wealth and civilization of the nation, is soil fertility. Therefore, any system of agriculture that will conserve or build up the fertility of the soil is paramount to all other problems of national concern. It is peculiarly characteristic of American farming to largely disregard the baneful effects of soil exhaustion. As agriculturists we have been exceedingly prodigal. The almost boundless wealth of virgin soil has perhaps been responsible for this, but now the skimming process is practically at an end and we should lay the foundation for tangible work of soil building. This will logically rest in some form of animal husbandry. Of all classes of animals upon the farm the cow takes the least from the soil and returns the most to the farmer. Thus she is the true soil builder. Fertility follows the cow.

As examples of soil building we may profitably consider systems of farming followed for generations in older countries where farm animals are made the dominant feature of the farm. Despite the poor soil at the beginning they are now producing more than double the amount of wheat per acre that we can show from our practically virgin soil. The average wheat production of the United States is 13.75 bushels per acre; of Great Britain 32.6 bushels, and of Oregon 19.8 bushels. The larger portion of the Oregon production, however, is grown on summer-fallowed land, hence the yield represents a crop every other year. The large yield of wheat in European countries is the result of a practical utilization of all forms of plant food. Millions of tons of feed-stuffs are fed in those countries, largely for the purpose of building up the soil. Ship loads of cotton seed and linseed cake annually leave our shores to enrich the farms of Europe. One of the favorite methods of soil building in those countries is the liberal feeding of farm animals upon these highly concentrated feed-stuffs in the open field. This is scarcely thought of in our own country.

The dairy cows of these countries are largely maintained upon American-grown feed-stuffs. This feed should be fed at home. The European farmer in purchasing feed for stock considers its plant food value as carefully as its nutritive value. When he purchases a ton of bran he estimates that it is worth $14.27 as a fertilizer for his soil; a ton of oil meal, $25,69; a ton of cotton seed meal, $30.15; a ton of alfalfa hay, $10.50, etc. These values are based upon what he has to pay for artificial fertilizers. Thus he fully realizes the importance of rigidly conserving the waste products of the stable. The amount expended annually for artificial fertilizer in the United States is estimated at $145,000,000.

The cow is the conservator of wealth because she manufactures from the crude feed the highest priced product of the farm without drawing much from its storehouse of fertility, or in other words the cow fattens the land. If the waste product of the dairy herd is carefully conserved and applied to the soil and the butter fat only is sold there is practically no soil exhaustion in this system of farming. When the legumes are grown and fed to the cows the nitrogen content of the soil is greatly increased. A good cow well managed will give a larger return for food consumed than any other farm animal. It therefore makes it practical for the dairyman to purchase liberally concentrated food for the herd. This is one of the very best means for maintaining the fertility of the farm. Many dairymen fail utterly to comprehend the value of the compost from the dairy herd. Some years since a very carefully conducted scientific investigation was made to determine the fertilizing value of the compost from a well-fed dairy cow, for one year. It was estimated that the value of this compost ranged from $28 to $35 on an average, in this instance, $31.50. Oregon has 175,000 cows and if these cows were properly fed and at the same ratio of value for compost it would represent the astounding sum of $5,512,500. Thus we can readily see how the cow fattens the land. One of the problems which confronts the dairyman is how can the maximum percentage of this compost be saved. Under present dairy farm practices a very large proportion of the value of this plant food is wasted, especially is this the case with the liquid portion. Many systems for taking care of the by-products of the dairy-barn are followed, but perhaps the most generally successful is the liberal use of straw bedding for an absorbent and hauling the waste material directly to the field. This method is the most satisfactory whenever it is feasible to put in operation. But unfortunately in the humid section of the state, it is largely impracticable during the winter months. Thus it is generally necessary in Western Oregon during the winter months at least to store the compost for future use. If but a limited quantity of straw be used and the compost is wholly supplied from the cow stable a covered shed would be the best means for conserving it. But if much straw is used and the compost from the horse barn is mixed with that from the cow stable, then care must be exercised that excessive fermentation does not seriously impair the value of the manure. Under those conditions it can be stored in the open, but if stored under a shed it must be watched closely and when showing a tendency to overheating water should be applied. Manure that is firefanged has practically lost all of its nitrogen. Perhaps what is the very best plan for storage is to keep the compost under a shed, have the stable floors so that liquids will drain into a tank located in the shed and the liquids pumped occasion-

ally over the compost. If the floors of the stable are to be flushed with much water arrangements should be made whereby the water containing but little plant food may be diverted in another direction. It must be remembered that but a small proportion of the plant food in feed stuffs is appropriated by the cow, hence the residual matter in the form of compost should be carefully conserved. It should also be remembered that the liquid excretion is more valuable than the solid and provision should be made to save as much of this as possible, either by means of absorption or through a system of drainage.

A good practice is to sprinkle the gutters and stable floor with gypsum, land plaster, daily after cleaning. This has a tendency to fix the ammonia compounds and deodorize the stable.

The utilization of skim milk is an important question to many dairymen. Immense annual losses occur from improperly feeding this valuable by-product of the dairy. The greatest mistake usually occurs in the quantities fed. For example, when skim milk is fed to hogs in the proportion of three parts of milk by weight to one part of grain it is worth a good deal more than it is when fed in a larger ratio. In a feeding experiment with hogs results have shown that when three pounds of milk are fed with one pound of grain, 327 pounds of milk will save 100 pounds of grain, but when six pounds of milk are fed with one pound of grain, 574 pounds of milk are required to save 100 pounds of grain. In two feeding experiments conducted at the Oregon experiment station skim milk proved to be worth 85 cents per cwt. Four lots of hogs were used in the experiment. One lot was fed wheat chop, another lot was fed wheat chop and skim milk at the ratio of about three pounds of milk to one pound of chop. The other two lots were fed in a similar manner, except ground barley was substituted for the wheat. The two lots fed milk with the grain gave much the better gains, and the commercial value of the grain saved made the milk worth 85 cents per cwt. This, however, was rather a phenomenal showing for skim milk, but with reasonable care in feeding, skim milk is worth at least 50 cents per cwt. for growing and fattening hogs.

Sweet skim milk and sour milk have about the same value as food material, although some experiments show a very silght advantage in behalf of sour milk.

Butter milk, when no water has been added, is equally as valuable as skim milk for hogs. Whey is also good feed for hogs when fed in connection with grain. Two pounds of whey is equal to about one pound of skim milk. Skim milk is a valuable poultry food when fed with grain. Poultry will give larger returns for milk consumed than any other farm stock. It is especially good for growing chicks and laying hens.

The great consumer of skim milk upon the farm is the calf. It is here where milk has its great direct and indirect value. The greatest need of Oregon agriculture is more cows. Thus the hope of getting more cows rests with the growing of heifer calves. Excellent calves can be grown on skim milk. The difficulty, however, is generally in feeding irregularly, too large a quantity, or feeding it cold and sour. Skim milk should be fed warm and perfectly sweet to the calf. Volumes have been written upon the subject of growing calves upon skim milk, but despite this fact but very few farmers realize the full value of skim milk in feeding calves. Too many stunted, pot-bellied calves are in evidence on dairy farms. There is no excuse for this. If milk be fed in proper condition to calves they should grow well and look sleek and thrifty. The best supplemental grain with skim milk for calves is whole oats.

Cows carefully selected, given good care and the by-products properly utilized, will bring more direct and indirect wealth to a community than any other branch of agriculture.

MORE FLESH AND EARLY MATURITY IN MEAT ANIMALS.

If the fat stock shows have shown anything, they have shown, by the premiums awarded and the decisions of butchers, that the thick-fleshed animal that finishes up quickly as possible is the one that is in greatest demand by the meat world.

Both in sheep and cattle, breeders have striven, first of all, for size, regardless of the thickness of flesh and the ease with which these animals fatten into prime condition for slaughter. Awards seem to indicate that this has been a great mistake. Size, of course, is important; and, where economical growth is made, a certain amount of this quality is essential; but what is equally or more essential is that the animal be covered with thick flesh; that it be "meaty," and that when cut it shall give satisfaction. With this thickness of flesh has been and is usually associated comparatively early maturity. It is possible, of course, to get the animal too small and to have the maturity come too soon in life; but, on the other hand, it is possible to do just what people have been doing when they have selected for size, without regard to thickness and early maturity. A medium-sized animal that shows these desirable qualities is rather to be preferred.

Whether it is a mutton sheep or a beef animal, the entire top part is a general indication of what the animal is. It should be of equal width through the chine, through the ribs, through the loin, and through the rump, from side to side. This sort of an animal indicates that the thick muscle runs from one end of the animal to the other. Those that are narrow over the rump, wide over the loin, narrow in the chine, long in the neck, are not heavily muscled. If they are wide in front and narrow behind, they are not thick-muscled. Those that have protruding rear ribs are not thick-muscled, and if they are not thick-muscled they are not early maturers either. Of course, with thickness through the top part of the body, we like to see an animal that stands near the ground and that has the curved rib extending from the top of the body to the bottom. This formation usually goes with thick muscles and with the early maturity for which we are looking.

That improvement is being made in the direction of thickness of flesh and early maturity is evident, now that feeders are talking of discontinuing the two-year-old class, in which the show rules permit an animal to be from thirty-six to thirty-nine months of age when shown. This is being talked of by leading showmen, because the proper type of an animal will reach the prime stage in life, as regards fleshing and finishing and

economy of production, about twelve months before the regular two-year-old show class is reached. Keeping them to show in this class is simply doing something that has no economic value, and is misleading to the public in so far as this is concerned. The move is a wise one; and we hope to see it carried out, and the thickness of flesh and early maturity, which are now held up as points to be sought in cattle, encouraged by all meat producers.—D. O. Gaumnitz, Minnesota University Farm.

THE FARMER'S OPPORTUNITY.

There is no excuse for the farmer of even moderate circumstances to use other than pure-bred, good quality of sires in his breeding of horses, cattle, hogs, sheep or poultry. There is no apology acceptable in this advanced day and age if live stock improvement for the scrub sire, or even the low quality of pure-bred sire, to have a place on any farm; his existence is absolutely without warrant and a heavy penalty should be imposed on the owner or harborer of such animals in the interest of general live stock advancement.

In the majority of public sales of pure-bred live stock there are a number of males that sell for prices away below their actual values. They are not quite up to the standard in flesh perhaps, or they possibly are a little coarser in general character than the average; some little imperfection, possibly, or unfashionable feature in strict breeding quality prejudices the fancy and the animal is not looked on with favor by the breeder of pure-bred animals. Thus a large number of otherwise very valuable animals are sold at low prices at the sales. Just such animals as the common farmer should own; just such animals as the common farmer can afford to buy and use on his grade stock and from which service build his farm stock rapidly into the very desirable and profitable high grades.

Never in the history of improved live stock breeding have there been greater opportunities offered the common stock raiser to take advantage of improved blood than now and in the recent years just past, and at prices that everyone can afford. When young bulls of the standard beef breeds can be bought at $100 there is in the opportunity a bargain for the buyer, because this is getting down pretty close to the cost of the beef animal, say nothing of the money to be made by his use in the graded herd. The time has arrived when the country is supplied with good breeding animals, and plenty of them. There is no further excuse for the grade sire in any line of live stock. Prices are now within the reach of every owner of breeding stock. Improvement should be rapid in all the grade herds. The ownership of anything but the pure-bred sire should be stamped with dishonor and shame.—Twentieth Century Farmer.

FANCY CHEESE.

We acknowledge receipt from the American Sheep Breeders Company of a little book by Professor Publow, of Cornell University, on Fancy Cheese in America. It deals with all of the different fancy cheeses and gives instructions for making them—some forty varieties in all. It is a practical handbook, and will be found of considerable value by anyone interested in the subject. It sells for seventy-five cents, and can be ordered through this office.

Cream Separators, all sizes and prices. O. J. Weber Co., 225-227-229-231 East Sixth street, Los Angeles.

We talk about the great wealth that comes from our gold mines, but forget to note that the annual income from the cows of the United States is $700,000,000.

Don't overstock your dairy in starting, and keep a careful record of each individual from the day she takes a place in your herd. Her record will prove whether you keep her or sell her.

Peanuts, like many other legumes, are excellent for thin soils and for feed for animals. Every swine breeder knows their value for pork. Where market can be had, peanuts are found profitable as a money crop.

WHY NOT DO IT RIGHT--"Let the Hart-Parr do Your Work"

Experience teaches that the proper way to prepare land to get best results, is to plow deep, tear up the clods and reduce the surface as fine and level as possible, so as to prevent evaporation of moisture.

Proper preparation of the seed bed is one of the things which goes a long way to assure at least a fair return, even in the driest year.

So, why not do it right?

THE "MODERN FARM HORSE" will furnish the power. The plows can be sunk just as deeply as desired and the heavy traction pulverizers will leave the land level and in shape to take in and hold every drop of moisture which falls on it.

Some sections which cannot be properly farmed by the use of horses will return good crops when handled with a tractor, because in that way the land will be treated as it should be.

DO IT RIGHT—

Buy a Modern Farm Horse Now.

Let us tell you more about this "Modern Farm Horse," and its advantages on your farm. Mail us a postal card—we will do the rest. Two sizes, 30 H.P. and 45 H.P.

"It is up to us to tell you why ours is the best,
But it is up to you to put it to your test."

CONTENTS THIS WEEK

ALLIGATOR PEAR, Cover.

ENLARGED HORTICULTURAL POSSIBILITIES, 35.

CITRUS AND TROPICAL FRUITS.—Spraying for the Citrus Mealy Bug: 36, 37, 38.

DECIDUOUS BUSH-TREE FRUITS.—Horticultural Training for Boys; An Iowa Plant Breeder; Harvesting the Fruit Crops; Figs in California: 39, 40.

HOME GROUNDS BEAUTIFUL.—Planting a Lawn, and Care: 41.

GARDEN AND FIELD CROPS.—Breeding Pedigreed Potato Seed; Cabbage Culture: 42.

LIVE STOCK AND DAIRY.—Utilizing By-Products; More Flesh and Early Maturity; Farmer's Opportunity; Fancy Cheese: 43, 44, 45.

EDITORIAL.—Lemon Tariff; Census Figures; Demonstration Train; Farmers' Institutes; Frost; Citrus Fair: 46.

AGRICULTURAL NEWS NOTES OF THE PACIFIC COAST.—Northern, Central, Southern, The Coast: 47.

PRACTICAL POULTRY CULTURE.—Profit in the Poultry Yard; Why Chicks Die in Their Shells; Shipping Crate; Practical Hints; Southern California Poultry Show; French Breeds; Prevention Better Than Cure; A Few Dont's: 48, 49, 50, 51.

IRRIGATION AND FORESTRY.—Irrigation Investigations; California Dry Farming: 52, 53.

QUESTIONS AND ANSWERS.—Liver Trouble; Cutting Lemon Buds; Product for Wet Land; Planting Sweet Potatoes; Transplanting Peach Trees; Date Palms; Poisoning Gophers; Roupy Hens for Breeders; Number of Ducks; Orchard Planting; Tincture of Aconite: 54, 55.

VETERINARY.—Contagious Eye Disease; Bladder Trouble: 55.

TIMELY RANCH SUGGESTIONS.—Alfalfa Experience; Eradicate Johnson Grass in Summer; Value of the Garden: 56, 57.

GENERAL HOUSEHOLD NOTES.—Like Mother Used to Make; So Long as Life Shall Last; Asparagus Recipes; Homely Hints; Nervous Headache; Measure of Beauty; Pineapple Confections; Fun for Evening Guests; Orange Marmalade: 56, 60, 61.

PRODUCE MARKET.—Los Angeles Market, San Francisco Market; Deciduous Market; Citrus Market: 62, 63.

LEMON TARIFF.

The fine Italian hand of the lemon importer is already being manifested in the tariff revision effort. A writer in the January McClure's makes an attack on Senator Flint because of his work for the cent and a half tariff which now obtains. He charges that Senator Flint and those interested were actuated by a desire to "establish a monopoly on an article in which there would be constant shortage, thereby enabling them to regulate prices at their pleasure." The aid of Senator Aldrich was secured or rather his "permission" for the cent and a half tariff was secured because of his need of the votes of Senators Flint and Perkins on other features of the schedule. The writer also charges that Senator Flint based his appeal for the 50 per cent increase on four claims:

"1. That lemon culture in California was facing ruin.

"2. That four per cent or less was all that a grower could expect to make on his investment, under the one-cent tariff.

"3. That Italian competition was ruining the trade.

"4. That if the Sicilian-imported lemon were shut out of the American market California could and would extend its lemon groves until in a few years, it would be supplying the whole country with lemons at a reasonable price."

That the first can be substantiated is plain to every lemon grower in California. To set forth all the facts in hand to prove it, however, would require this entire page and several others, but that hundreds of acres of producing lemon orchards were rebudded to Washington Navels or Valencias is so well known that enough witnesses could be taken to Washington to more than fill all the hotels in the city. Had this industry been as profitable as the writer in McClure's would make out, this changing over of orchards certainly would not have occurred.

As to the second point it is charged that Senator Flint made, we frankly do not believe that the Senator stated it in these words. Later in his article the writer is more honest, using "The average profit which lemon growers have received is about four per cent on their investment." The average of orchards is vastly different from what a man may expect of his orchard in best condition, and we believe the four per cent net return on investment is as much as the industry will average.

On the last point, the extension of the lemon groves of California sufficient to meet the demands of the country (13,000 carloads this year of which California furnished about half) this can be made good if the industry reveives encouragement. That there is possibility of production in California of more than 13,000 cars of lemons goes without saying, but if the encouragement which has been given to the industry is removed and a few hundred more acres are budded over to oranges, the time will never arrive.

The writer backs up his claim of great profits received by the growers by referring especially to reports of dividends of the Limoneira and Leffingwell groves. As to the correctness of these statements we have no information, but assuming that they are correct, we ask what is proved. The returns of two of the very best managed lemon properties in the world furnish no proof as to the average which the industry has to carry. The writer refers to the "great Leffingwell ranch. On this ranch the soil is difficult and water expensive," as reason why its profits are not equal to Limoneira. That is true in a greater degree on other properties.

As to the proof of the hardships which "this iniquitous lemon tariff has imposed," says the writer, "This fruit which is a necessity in cookery and flavoring, but is an essential in the sick room and in institutions and in medical practice," is quoted at prices obtained last October. Then they sold for "$6.00 and $9.00 per box, one car selling as high as $10.50, $10.85, $11.87½ and even up to $12.00." This was because "Californians now are getting control, thanks to the tariff, and they have lifted the price 33 1-3 per cent above the utmost fears."

Bear in mind that these quotations were made in October when neither Italy nor California were able to cut fruit because of the season, yet the McClure writer would carry the idea that a cent and a half a pound duty was sufficient to accomplish that result. As well refer to strawberries at $1.00 per basket, which our New York friends often pay out of season, and figure the profits of the strawberry industry from that one quotation. Last week's Cultivator gave prices of lemons in New York on December 30: "Trail, $2.70; Canyon $2.65; Our Beauty $2.50." In Pittsburg: "Greenleaf $2.65." Cleveland: "Palm Tree $2.40; Commercial $1.50; Knight $2.15." Boston, January 3: "Market higher on lemons. Whittier $2.85." Deducting freight, auction charges, boxes, packing, and other expenses back to the orchard expense, and we believe the four per cent on investment would be gone in everyone of the orchards from which this fruit was picked.

Unfortunately, there is one sting in the article, that is, "A sequel to the lemon tariff which does not lack grim and sardonic humor, in other words, the advancing of the freight rate which the railroads have insisted upon and have finally won." This is claimed to be the rake-off which secured the passage of the 50 per cent increase.

CENSUS FIGURES.

The thirteenth census of the United States shows that the state of California has advanced in population rank from twenty-first place in 1900 to twelfth place in 1910. This was secured by an increase of 60.1 per cent, which placed the state above the two million mark—to be exact, 2,377,549. Ten years ago the population was 1,485,053; in 1890 it was 1,213,398.

In the matter of density of population, California has opportunity for increase. The population per square mile in 1890 was 7.08; in 1900, 9.5; while at the present time it is 15.2, twice the density of two decades ago. Rhode Island shows the greatest density of population in the Union, with 508 per square mile; Massachusetts has 418, New Jersey 337, Connecticut 231, and New York 191—the above in round figures.

Our percentage of inrcease this decade was 60.1, while Oregon, with 672,765, and Washington, with 1,141,990 people, both showed a greater percentage, the former 62.7, while the latter showed the greatest of any state in the Union—120.4 per cent. This high percentage means, however, an actual increase of only 623,887, while California's actual increase was 892,496, or over a quarter of a million more than Washington. Arizona shows a perecntage of gain of 66.2, which represents an increase of population of 81,423, making the present population 204,354. In population density, Arizona is not crowded, showing 1.8 people per square mile.

ANOTHER DEMONSTRATION .. TRAIN.

The Salt Lake Route has taken up the Demonstration Train idea, and will have a train leaving Salt Lake City on February 8 which will tour Utah and Nevada for nearly thirty days. The train will carry experts from Utah College of Agriculture, University of Nevada and University of Idaho. Later it is stated that a similar train will be made up for the lines of the Salt Lake in California.

This train will be different from all other educational trains operated in the West, in that it will carry a car of blooded livestock. Particular attention will be given to the gospel of dry farming. Besides the cars of exhibits and those for the accommodation of the experts, one car will be fitted up for stereopticon lectures.

FARMERS INSTITUTES.

J. B. Neff, Conductor of Farmers' Institutes for Southern California, announces dates for the Imperial Valley institutes as follows: Calexico, January 30; Heber, January 31; Holtville, February 1; El Centro, February 2; Imperial, February 3; Brawley, February 4.

Mr. Neff is also planning for a series of institutes along the line of the Santa Fe east. This will begin soon after those in Imperial Valley.

Notwithstanding more general provision for frost protection than in any previous season, it now looks as if the season may pass without its extended use. We say "extended use," for on the morning of January 1 the temperature went in a very short time, in one of the orange-producing sections, to as low as 24 degrees. In the larger producing sections 28 was the lowest recorded, and it usually stood around 30. Therefore, the indications are that, with fruit as far advanced as it is this year, it is not probable that cold will come this late in the season sufficient to cause any injury whatever. Puffing and some early dropping may affect some fruit, but on the whole a great citrus year is promised.

Northern Californians, especially commercial bodies in the city of Sacramento are making great preparations for the Northern California Citrus Fair which is to be held in that city February 16-18 as an adjunct to the Western Fruit Jobbers Convention. Much space has been engaged for displays not only of citrus fruits but of raisins and all kinds of fruits, dried and fresh. It is planned to show the productive capacity of Northern California orchards to these fruit sellers.

As we go to press there is a little promise of rain, but unless it comes in great quantities we believe the wise orchardists and vineyardists will fill their ground with water by winter irrigation—where water is obtainable. In sections which secure water during the rainy season or depend upon waste of storm waters from streams which are dry in summer, it is good insurance to have the ground filled with water for crops next summer.

Upon recommendation of P. J. O'Gara, the Rogue River Fruit and Produce Association has ordered of a Cleveland firm arsenate of lead for the coming season's spraying.

Agricultural News Notes of the Pacific Coast

Northern California

Healdsburg hop growers are selling at 16½ cents.

Roseville is making an effort to secure a cannery.

Some orchard property at Healdsburg has changed hands at $1,000 per acre.

The Woodland Creamery averaged for butter fat during the entire year 34.9 cents.

There is one automobile registered for every fifty-seven inhabitants of California.

Winters, Yolo county, reports an orange tree averaging fruit fourteen inches in diameter.

Oroville's postal savings bank, the first in the state, has been duly opened and is ready for deposits.

It is announced that the Orland Distributing System will be completed in the next five or six weeks.

A barge of 15,000 sacks of barley sank in the Sacramento near Grimes. The loss will be about $10,000.

Another colonization scheme is under way for Sutter county. Ten thousand acres are to be subdivided.

Seventy thousand acres of tillable land has been eliminated from the Modoc Forest Reserve, and 182,000 acres added.

The state agricultural association will ask the legislature for $300,000 for erection of buildings at the state fair grounds.

Hop growers have formed a co-operative marketing organization, and they hope to dispense with middlemen's profits.

Prof. E. H. Hageman of the State Farm at Davis is giving short course creamery instruction to students at San Luis Obispo.

The Yolo county horticultural commissioner is putting up a strong fight against Johnson grass, and urges cooperation on the part of all.

The rice harvest on the Balfour-Guthrie ranch, near Gridley, has been harvested, and was of excellent quality, and the yield satisfactory.

Santa Rosa has one poultry farm with 600 laying hens, which returned a profit of $874 in three months. This is $6.76 per day over cost of feed.

The directors of the Cloverdale Citrus Fair have fixed upon Tuesday evening, February 21, as the opening date of the nineteenth annual citrus fair.

Mr. C. L. Mitchell, who has been dairy representative of the United States Department of Agriculture in California for two years, is to be succeeded by Mr. T. F. Corneliusen.

At a recent meeting of the Debris Association of the Sacramento Valley it was reported that an injunction had been issued against the Pennsylvania Dredging Company of Sutter county, to prevent debris from reaching the river.

The Chico local of the Farmers Union expects to enlarge its marketing field during the coming season, and is making an effort to secure greater membership among the producers of fruits and vegetables. A packing house and warehouse are a part of the scheme of enlargement.

Central California

Estimates are that Turlock cantaloupe production will be greater than ever.

Kern county claims some of the finest samples of cotton ever produced in the world.

Dinuba, Tulare county, closes the orange shipping season with forty cars to its credit.

The uneasiness over the rain situation is causing all holders of hay to demand long prices.

The withdrawal of 14,000 acres from the Monterey National Forest throws open for settlement good agricultural land.

Santa Clara Valley seedmen claim that grocers and seed men the world over are handling seed grown in that valley.

A basket factory, in which small berry baskets will be manufactured, has been started at Gilroy, Santa Clara county.

Shippers of Santa Clara county are planning for a canal between San Jose and the bay, the cost to be about $300,000.

Prunedale, Monterey county, reports most of the grain sown, though some of the drier lands are awaiting wet weather.

Pomona Grange, of Santa Clara county, met in San Jose last Saturday. The Master of the State Grange made an address.

Visalia's record on the weather sheet for 1910 shows 322 days of fair weather, 27 days of rain, and 15 days of fog; 32 days of frost.

Even the section of the San Joaquin valley which has a rainmaker regularly employed does not seem to be receiving an excess of moisture.

An Italian at Red Banks, Tulare county, grafted ten acres of vines, and of 4,000 grafts only three failed to grow. He maintains he holds the record.

Canneries at San Jose report the 1910 pack of canned fruits larger than that of last season, but hardly up to that of 1908, which was the largest ever.

Stanislaus county, with its great increase in dairying, and also the excellent showing in the census, feels more pride than ever in its great irrigation system, which is given much credit.

The Irrigation District Association of California recently held a meeting at Manteca, San Joaquin county, and adopted a constitution. The next meeting will be held in Sacramento in January.

The Monterey Peninsula Poultry Association has been organized, with a membership of twenty-four, which represents the ownership of about 16,000 fowls. The President is Mr. Frank Greenwood, of Monterey, and the Secretary, Mr. W. A. Geards, of Pacific Grove.

The stockholders of the Salinas Creamery Company elected the following directors for the coming year: Duncan McKinnon, president; E. P. Alexander, E. Hitchcock and J. H. Menke. The First National Bank was elected treasurer, and C. J. Wiseman secretary.

Southern California

Riverside shipped 205 cars of holiday oranges.

The Driving Club at Hemet, Riverside county, held a matinee on January 2nd.

Beaumont boosters maintain lands in that section offer ideal apple-growing conditions.

The Highway Commission of Orange county recommends bonds to the extent of $1,400,000.

Highland, San Bernardino county, claims top notch price on orange shipments to date.

The sugar company at Oxnard, Ventura county, is constructing a 35,000 barrel oil tank at Hueneme.

The Orange County Dried Fruit Association still has a quantity of apricots which it is holding at 12 cents.

A new sugar company has been formed at Santa Ana on a co-operative plan. It is capitalized at $1,000,000.

Cotton picking in the Imperial Valley is still progressing, many growers estimating the total output at about 8000 bales.

The pre-cooling plant at San Bernardino is having its capacity increased by the construction of a 700-foot icing dock.

Whomes and Boehrman of Anaheim have already shipped two cars of sweet potatoes to Portland, Oregon. The sweet potato growers of Orange county have found good returns this year.

Orange growers of Southern California are watching with interest the shipment of oranges which went by water and Panama Railway. Report received is in effect that it is in best condition.

Farmers of El Centro, Imperial county, held a meeting last Saturday addressed by the president of the Farmers Union, Professor Packard and Professor Taylor of the Department of Agriculture.

One of the biggest ranches of Ventura county known as Rancho Santa Clara del Norte, is gradually being broken up, about 25,000 acres of its finest mesa land having been thrown on the market recently.

A suit which may be far reaching has been brought by the Santa Ana River Development Company against water companies mostly in San Bernardino county, to determine matter of water rights for a distance of forty miles along the Santa Ana.

Over 10,000 cows are being milked in the Imperial Valley and the dairy production of butter is about 7000 pounds. The live stock is increasing in numbers so largely that but little hay will be shipped out this season.

The forest service which has to do with the reserves in the Sierra Madre is planting more extensively of pine tree seed than in any former season. It is in the interests of water conservation rather than for timber purposes.

Orange packing houses are settling down to the regular work of the season's pack, though at present shipping is rather light because of large stock accumulated in eastern markets during zero weather when fruit could not be moved.

The Coast

Hogs are still quoted at nine cents at the Union Stock Yards, Portland, Oregon.

The sugar factory at Waverly, Washington, has been closed and it is reported, permanently.

Minnesota capitalists will plant some 18,000 acres of land to orchards near White Salmon, Washington.

The Highland Pumping Company is installing a plant which will irrigate 5000 acres near Twin Falls, Idaho.

The prairie country of Colorado reports the driest summer and fall in the memory of the oldest inhabitant.

Taking its cue from the Spokesman Review of Spokane, Simms, Montana, proposes to install a Country Life Hall.

The largest irrigation ditch contract yet awarded in Montana is to be for the construction of a canal near Malta.

The two states of Oregon and Washington report 2500 bales of hops yet to sell with price near the 16½ cent mark.

A hog grower at Chelan, Washington, recently butchered two hogs eight months of age which weighed dressed 559½ pounds.

Water users at Salem, Oregon, have filed articles of incorporation under the title of Central Oregon Water Users Association.

Whitman county, Washington, reports "largest acreage of fall wheat ever sown in the county." Conditions reported so far are very favorable.

Four thousand acres of fine land on the Snake River near Medbury, Idaho, will be irrigated by waters secured from the One Thousand Springs Company.

Freewater, Oregon, is much puffed up over Christmas strawberries produced in that section. The production, however, is only one small basket.

The North Yakima Poultry Show will be held next week beginning January 16th and extending to the 21st. Miller Purvis of Illinois will be the judge.

The irrigation of 30,000 acres of fine land is to be secured by the construction of a 32-mile canal near Milton, Oregon. The ditch will cost about $250,000.

The forestry department will plant 1400 pounds of walnut seed and 1300 pounds of red oak acorns in the burned over section of northern Idaho and eastern Oregon.

A meeting was recently held in the Throne Room at the Capitol in Honolulu to consider the five cardinal points of conservation, right to use lands, waters, forests, and minerals, and the safeguarding of public health. It was held under the auspices of the Board of Agriculture and Forestry.

The wheat production of the state of Washington during the past year brought to the state $19,970,000, an average of 77.8 cents per bushel. During the same period Oregon's returns were $13,788,000, or an average of 84 cents per bushel. Idaho's production during the same period netted $9,074,000, while that of Montana was $9,081,000.

Will be ready early in January, our

1911 SEED CATALOG

If your name is on our list, a copy will be mailed to you. If it is not, please send us your address for a copy. It is a good one, well worth having; sent free and postpaid. If you have any friends to whom you would like us to send catalogs, we will gladly do so, if you will kindly give us their addresses. And if you will send us five or ten of them, we will send you, for your trouble, a 5c packet of our best seeds, postpaid, for each five names you send. We have secured the California agency of the

Prairie State Incubators

The best—bar none. Carload to arrive this week. Come in and see them—or send for Prairie State Catalog. We also have a carload of the

Baby Buckeyes
50-Egg Incubator for $7.00

Did you ever hear the like? And with this guarantee, too: "Purchaser can operate it for forty days, and if it does not meet with his entire approval, it may be returned to us and the price paid will be promptly refunded." They will go like hot cakes. If you cannot come in, send for a Buckeye Catalog. "Anybody can hatch chicks with a Buckeye."

I'll Start You in Poultry on the Make-Good Plan

—Set you up in a paying business all your own—a business you can control and expand indefinitely—one you can operate on little capital and in small space—one that will give you real independence, pleasure and profit. Mail me a card to-day for my book containing the remarkable terms on which I am selling Queen Incubators and Brooders, freight prepaid. I have started over 61,000 people on the road to success. The Queen goes out on the make-good plan, the most liberal ever offered on a high grade incubator. My 1911 Poultry Guide and Catalog explains terms fully. It's a down-to-date poultry book, practical, concise, helpful—best book of the kind published. Write and let me mail it to you free.

WICKSTRUM, Queen Incubator Man, Box 53, Lincoln, Neb.

Practical Poultry Culture

PROFIT IN THE POULTRY YARD.

It is with great interest that I read in the Cultivator regarding more profit in the poultry yard. I often find some one's method of feeding and caring for chicks to be of great help to me and I think we make a great mistake in not taking more time to go out and visit other plants. We may see in going from one to another so many little things that we never thought of, at the same time practical and useful. Let me say to any one intending to go into the poultry business to first look the ground over thoroughly and see what a man has to do to feed and care for a flock of from five hundred to one thousand baby chicks. This will give not only an idea of the work, but will furnish material for much thought.

Poultry business in a way seems to be different from other lines. One will go out and see some fine large flock of pure bred birds, perhaps a thousand or more as the case may be, all uniform in color and size, and it will appeal to any lover of birds at once that he can enjoy such a flock. Often he will see no good reason why he could not do as well in producing them as the other has. So he looks the plant over and it looks as though all the requirements necessary are three or four incubators and a few simple brooders to decorate his place with a flock. Many have probably noticed the results of about nine out of ten that start in to build up a poultry business without experience. I have had years of experience in raising poultry, have hatched and raised chickens in all parts of the United States and north of the states in Canada where it gets cold. I consider this the ideal spot to produce poultry.

I breed White Minorcas for layers and they do well for me. I consider the poultry business a good investment and if one will start in with twenty-five or thirty good pure-bred birds and try to raise three or four hundred chicks the first year, and increase his flock from year to year, he is always on the safe side, and will win in place of losing. It will soon be discovered that there are a great many little details to be closely looked after.

I am often asked what I feed. The only answer I can give is this: feed anything a chicken likes best and change about in feeding often enough so they may not get "off their feed." Green feed I find to be one of the essentials for poultry. Without it birds confined in pens will not give results. Green food is one of the most natural things a bird ever looked for.

Profit in the poultry yard means that the hens must have a range outside to rustle the profits. I mean this for egg producing birds. If you are raising a larger breed of poultry for table use it is another proposition, for I think they may be raised to good advantage without range. I am not producing a large amount of poultry. I try to raise a few good ones. I seldom notice any write-up from any of our practical poultry men that raise them in large numbers. As a rule they let well enough alone and keep busy gaining profit from the poultry yard.

In conclusion let me repeat to any one becoming infatuated with the poultry business simply from observation of the other fellow's fine flock, just interview that man and a few more practical workers and look over all the little details fully about these plants and you may discover some weak point in your former idea of gaining profit from the poultry yard.—Daniel Webster, Rialto.

WHY CHICKS DIE IN THEIR SHELLS.

An inferior incubator frequently causes chickens to die in the shell, but in the majority of cases the fault lies with the poultry keeper and not with the incubator maker.

When an incubator of a certain make is known to be reliable, and when thousands of machines of the same make are hatching 90 per cent of fertile eggs in all quarters of the country, it is altogether improbable that unsatisfactory hatching is due to any flaw in the machine which we happen to have, for all reliable machines are fully tested before they are sent out from the works.

In nine cases out of ten we have to look elsewhere for the primary cause. To the question, Why do so many fully matured chicks die in the shell? it is impossible to give a definite answer that will cover the various reasons, but if a vague answer were enough to satisfy the inquirer, it might be: Chickens die during incubation because they have not sufficient vitality to break through their shells.

First of all, the breeder should look to the stock birds. If there is a lack of vitality or health in either male or female, that alone would be sufficient cause for bad hatches. And the great difficulty that here crops up is that constitutional weakness in adult birds is not always apparent.

There may be hidden and wholly unexpected diseases which seriously interfere with the breeding power of the birds, or which are transmitted in an aggravated form to their progeny.

If these cannot be detected there is nothing to be done until it has been proved by results that there is something radically wrong, and that a change of stock birds must be made, and by the time this conclusion has been arrived at it is generally too late in the season to make any improvement worth talking about.

But the careful observer who has experience of stock birds can generally detect any inherent disease which might affect the fertility of the eggs or the stamina of the chicks hatched from them, and of course, all such birds must be kept out of the breeding pens.

In this connection a new use for trapnests has been found—namely, to ascertain the fertility and germ strength of the eggs laid by individual hens. If trap nests were more generally used for this purpose we should soon cease to find people satisfied with a percentage of dead chicks in every hatch as they are at present, provided the percentage is not very large.

Not all fertile eggs will hatch, but we could certainly increase the percentage by greater care in the selection and maintenance of the stock birds.

This, then, is the chief cause of chicks dying in the shells—lack of

Rural No. 2. PETALUMA, CALIF.

Incubators and Brooders

The evidence is conclusive that the PETALUMA is the best incubator buy that can be made. The best value for the money ever offered and is appreciated most by those who have had varied experiences with other incubators. Why? Because it hatches such large, strong vigorous chicks. More Petaluma Incubators were installed in the large hatcheries last year than all other makes combined. No other incubator in the world has a hatching record to equal the Petaluma.

Write for our Free Catalogue. It is interesting.

health and vitality in the breeding stock from which the eggs are produced; but we have here a vague, though comprehensive definition which needs to be expounded.

Lack of health and vitality may or may not be the result of disease alone, or at all; but it may be caused by age, youth or immaturity, by insufficient or injudicious feeding, by overfeeding, the use of fattening foods or unsuitable housing.

Now, we come to the consideration of secondary causes of the trouble referred to, and these are almost too numerous to mention. The eggs must receive due care between the time of laying and setting to hatch, for at all times the vital germ is frail and easily injured and killed.

When an egg is laid it is quite warm and of about the same temperature to the very core as if it were in an incubator for several hours, so it takes very little to keep it in this state.

If the weather is warm and the egg is left in the nest where it is sat upon by other hens that come to lay, or by stray broody hens, the temperature required to start the germ is fully kept up and there is every reason to believe that the germ does not begin to develop in the course of ten or twelve hours, and that when heat is afterward withdrawn the germ may be either injured or killed outright.

Hence we see the necessity for collecting the eggs which are required for incubation off the nests two or three times a day in summer and at least once a day in winter and spring, and it is also apparent that a broody hen ought to be kept out of the laying house, if we want to preserve the eggs for hatching unimpaired.

An egg can stand a fair share of rough handling without apparent injury while the germ is in a dormant state; but once the germ gets started, it must be treated with the greatest care.

The other causes of chickens dying in the shells at various stages in the period of incubation are usually due to careless manipulation of the incubator.

A common cause of the failure of fertile eggs to hatch is lack of sufficient ventilation. The fresh air supply depends to a greater extent than is generally known on the differences in the temperature of the air inside the machine and that of the room in which the incubator stands.

For some time past we have been hearing a good deal about "non-moisture" incubators, but it is not generally known that the difference between these and the older type of machine is that the older machine admitted a huge volume of air in the form of draught which absorbed a large quantity of moisture from the eggs, just as a stiff breeze dries up the roads after some rain has fallen, but this same draught took up some moisture from the trays and supplied it to the eggs, while on the other hand the non-moisture machines admit the air gradually; there is no current and the eggs retain their moisture.

This plan works very well in low-lying damp localities, but the old system of plenty of air and sufficiency of moisture gives better results in high and dry districts.

Too much moisture will also cause chicks to die in the shells, and a common error, due to inferior regulators or to carelessness and irregularity in attending to the lamps, is in allowing the temperature to vary very considerably.—Farm World.

SHIPPING CRATES.

Shipping crates should be light and durable. They should be commodious, large enough to accommodate the fowl or fowls to be shipped in them. Crates that are at least two feet in height are to be commended. A foot of ground or floor space should be allowed each fowl. A crate square or oblong is the usual shape and should be ventilated near the top on the sides. Handles may be added to assist those who handle the crate while en route.

The best material for a crate is white pine, for it is light and strong. The corners of the crate should be reinforced with posts as here is where the most strain will come in handling it. The cover may be fastened in with a padlock or a hasp or some device of one's own invention; but the padlock will prevent exchanging of birds during shipment.

It is a good plan to paint all shipping coops or crates attractive color, together with the name of your plant or your own name and address; for in this way you advertise your business. Have the words: "Return to" precede your name and address so your crates will come back to you. The express companies make no charge for returning empty crates.

It is a poor idea to use berry crates, dry goods boxes, or anything one can find in which to make his shipments. Such a course looks slovenly to the outside world and makes a poor impression on your customers. "What is worth doing at all, is worth doing well." Endeavor to use uniform crates, that appeal to the eye, and they will attract attention everywhere and bring you business wherever they go. —Successful Farming.

PRACTICAL HINTS.

It is one thing to produce good poultry and eggs, but it is quite another to dispose of same at a financial profit.

Good pure water, in clean dishes and fresh added, is necessary for growing chicks, and in fact all poultry should be well supplied.

Feed only what the hens will eat clean; scatter the grain in litter or spade it in the ground and make them scratch for it.

There is no "best breed," the one you prefer, the one that suits your ideal fancy will better suit your purpose, and you will get better results.

Learn how to feed, what to feed, and get acquainted with the needs of the hen, fortify against diseases and make every hen do her best.

Air-slaked lime scattered about the houses and yards is a splendid disinfectant, and will help to keep it sweet and clean and the flock healthy.

One of the most important points in chicken growing is to keep them growing. Every condition must be at its best and you must keep them so.

Put plenty of nests in the laying house and in a semi-dark place. The hens prefer this kind of a nest and will leave others to use the darker nest.

For the average person to make a success one breed of fowls is enough. There are many points in favor of one breed.

It is an easy matter to overfeed fowls, and poultrymen should bear this in mind. They often have the appearance of starving when they do not need it at all.

The male bird is half the flock, then how foolish to use one that is not up to the standard or idea you are aiming for. This means much to you and it is possible to improve faster

in this way than any other.

Poultry and dairy farming go well together. In fact, milk fed to poultry in all forms produces good results. Milk fed poultry in the fattening pens demand a fancy price over other fed poultry.

There is a difference in the hatching of different color shell eggs and from different breeds. If possible, to secure the best results, use eggs of one color and from one breed for each incubator or hen set.

Plan to raise more and better poultry this season. No breed will pay better than the one you have if it is suited to your purpose. It's the man behind the breed that makes them pay, as much or more so than the breed. —American Poultry Adv.

A little flaxseed meal in the food will help the old fowls to pass through moulting rapidly.

SOUTHERN CALIFORNIA POULTRY SHOW.

After months of sunshine and beautiful weather, the members of the Southern California Poultry Breeders' Association were somewhat nettled to have the downpour come during their show week. However, they are a forgiving bunch, and the show is generally so satisfactory that the mistake of the weather man was overlooked.

It's a good show. Something over 1500 birds were exhibited. A few of them are bants, but mostly utility breeds. Buff and White Orpingtons are strong classes, as are Barred and White Rocks. One of the most numerous, also, is the White Leghorns, and some very fine birds are shown.

White Wyandottes, which in some of the past shows have predominated in numbers, are not so numerous this year, but there are some magnificent birds in that class. The Reds are strong, while Black Langshans have a showing of especially large birds. A $250 Cornish fowl is one of the proudest aristocrats in the bunch as he stands wide and watches the common people.

The bantams, especially the Black Breasted Red Games, were a surprise in both numbers and quality.

Bronze Turkeys, as usual, were not numerous, though birds of fine size, vigor and form were cooped. Water fowl was a weak class as to numbers. Geese hadn't a single representative. Ducks were better, Indian Runners and Pekins being most numerous.

Owing to the great number of exhibits, double-decking was necessary, which did not do fullest justice to all exhibitors.

The judges were Judge E. Sites, of Elyria, Ohio; Judge George W. Masterson, of Duarte, and Judge N. E. Luce, of Los Angeles.

The officers of the association are: E. E. Emerson, president; J. Madison Wright, first vice-president; R. B. Hayes, second vice-president; A. H. Memmler, secretary; J. L. Harrison, treasurer; directors, C. C. Bonnell, Joseph E. Davis, H. W. Gunston and Henry Mumford. Besides the annual show, meetings of the organization are held monthly at the Chamber of Commerce building in Los Angeles.

The large tent annex houses some fine exhibits by poultry supply and feed houses. Of course, Ironmonger, successor to the Albers retail house of Los Angeles, is there with a full line. West Coast feeds and remedies occupy liberal space, and the Germain Company representatives are there with the goods. The Philo system is exemplified by a working model. It's a curiosity, but the poultryman usually shook his head and passed on.

The special cup awards are as fol olws:

Orange county challenge cup, largest exhibit from Orange county—Won by O. M. Robbins, Buff Leghorns.

Santa Clara county cup, offered by Santa Clara County Poultry Association, best display for Northern California—W. H. Bissell, Twin Oaks Farm, Livermore, on White Orpingtons.

The Colorado trophy, best display of Rhode Island Reds—J. L. Harrison, South Pasadena.

Los Angeles Chamber of Commerce cup, best ten birds in the show—A. A. Bamford, on White Rocks.

Ladies' cup, best pullet shown by a lady exhibitor—Miss Margaret Hale, on Black Orpington.

Ironmonger cup, largest display of poultry made by a novice—Hoyt & Lawyer, San Gabriel, on White Rocks.

Emerson & Mumford cup, best display of Barred Rocks—Fred Espe.

Ironmonger cup, best Barred Rock pen—A. C. Kullman.

Joseph E. Davis cup, best pen Barred Rocks by a novice—E. M. McCulloch.

Fred Espe cup, best display White Rocks—Emerson & Mumford.

WILL YOU STAND FOR SUBSTITUTION?

If you will, then you can be sold ANY OLD CHICK FOOD, and you will think you have made a satisfactory purchase. But if you are looking out for your own best interest you will always demand COULSON'S FOOD and insist on getting it.

Most dealers handle our food because they know it is the best. Some dealers handle an inferior food and trust to salesmanship to dispose of it.

By long study and careful preparation we have perfected a line of poultry foods and supplies which in every way meets the demands of the thoughtful poultry raiser. Our foods cost you no more than the inferior kind, but they are worth more because they contain the essentials of FEEDING FOR PROFIT.

Raise your chicks well, and half your battle for success is over. This can be accomplished by feeding the best feed—Coulson's Special Chick Food.

FRENCH BREEDS.

Houdans—Houdans are of French origin and very popular among that race as a table fowl, weighing seven pounds for cock, six for hen, and six and five with cockerel and pullet. They are mottled in color and bearded, with leaf comb, prominent nostrils, short strong legs, red faces, and white ear lobes.

Crevecoeurs—Crest and beard doubly ornamental, this breed, from France, are about one pound heavier than the Houdans. They have leaf comb, compact body, plumage rich, black and glossy.

La Fleche—Also black as to plumage; weighing eight and one-half pounds cock, seven and one-half hen, seven and one-half cockerel, six and one-half pullet. They are favorites with the Parisian marketman, and dress good meaty bodies; heavy thighs and long shanks, and altogether showing the finish of a bird destined for the table.—Rural World.

PREVENTION BETTER THAN CURE

A poultry bulletin issued by the Rhode Island Agricultural College recommends methods of prevention rather than treatment of poultry diseases. The turkey production in New England has been on the decline for several years, and especially in that state where so many turkeys have always been produced. This bulletin states that blackhead causes a great loss among the New England turkeys, and that this disease, like all others, is due largely to carelessness. The bulletin explains how the farmer and poultry raiser can save a whole lot of work and loss provided he gives the chickens and turkeys the proper feed and care. The treatment of disease is of little value, this bulletin states, after it gets into the flock.

A comparative test of the American plan of freezing eggs to preserve them with the method of treating with lime has been made by a scientific French experimenter. The refrigeration process is pronounced hygienically superior. At low temperature even when continued several months there is no perceptible change in the taste or properties of the egg, the yolk retains its position instead of falling to the lower end as in lime preservation, and the only change in appearance is a little greater wateriness. It is necessary, however, to keep the temperature about 2 degrees F. below freezing point, with the hygrometer as near 78 degrees as possible.

A FEW DON'TS.

Don't forget to paint the walls of the poultry house with a thick coat of whitewash.

Don't let another laying season go by without trying trap nests. They will tell about unprofitable hens.

Don't sell the best of the flock because you can catch them easier. Cull with judgment.

Don't put fifty fowls in a house built for half that number.

Don't buy screenings for feed. Buy good wheat or corn.

Don't mix in a few good birds with the culls when marketing, thereby expecting to get a better price. It works the other way every time.—Ranch and Range.

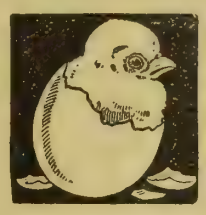
Huxley, the great English scientist, said that the development of the embryo in the egg was the most wonderful thing in the world, and yet, wonderful as it truly is, when studied from the standpoint of scientific inquiry, how many people living on farms have ever given this wonderful transformation any study? Three weeks of heat serves to bring life, bones, feathers, heart, brain and a marvelous organism out of the embryo, where the most powerful microscope fails to find anything of the kind in the beginning. The farmer is fairly surrounded by scores of deep mysteries like this, but familiarity in most cases has not aroused their interest in this wonderful phenomenon.—Hoards Dairyman.

The squab industry is yet in its infancy, and the possibilities are as great as ever, for there seems to be no limit to the demand. The rapid growth of squabs is another feature to be taken into account when one is looking into the investment part of this business.

It is a loss of time and money to try to keep several breeds of chickens unless one is prepared to keep them separate. Of course they can be allowed to run together during the seasons when eggs are not wanted for hatching; but this does not always work well, for each breed has its peculiarities. Some are more timid than others, and do not get their share of feed at meal-time. The different natures require different care. Mixing them is detrimental every time. One breed selected according to one's markets and facilities, is sufficient for the average farmer. To attempt more means more trouble for the owner and less comfort for the fowls if he tries to keep them separated.—Farm Journal.

The following lotion is recommended for wet eyes in pigeons: Solution of atropine, one dram; sulphocarbonate of zinc, two drams; water to make half an ounce. A few drops should be dropped into the bird's eyes twice a day.

Ernest Winslow, one of the most practical pigeon men in this country, advocates cleaning the lofts weekly, and also cleaning the nest boxes each time they are stripped of squabs. Air-slaked lime is then sprinkled in the boxes.



White Leghorns

A Standard Strain of Great Layers and Great Winners. None superior. Prices reasonable. Booklet descriptive of our stock and farm, containing recipe for mixing the best and cheapest egg-producing mash, sent free for stamp. Eggs, stock and baby chicks for sale. Also a grand lot of cockerels. On a separate farm, we have an extra fine lot of Buff Orpingtons, from which we can furnish stock, eggs and baby chicks at popular prices.

108-110-112-116-118 EAST 8TH STREET, LOS ANGELES, CALIF.

This open front door makes perfect ventilation

Mandy Lee is Miles Ahead

It is the only Incubator without a "Sealed," Air-tight Egg Chamber. It supplies the life-giving oxygen freely, draws off the carbonic acid gas, and is saving the lives of millions of chicks.

READ the story of the Mandy Lee triumph in our new catalog. Other incubators are already preparing to imitate and profit by our great discovery.

No guessing with a Mandy Lee

You cannot afford to buy an old-theory incubator which may go out of date and be discarded next year. You should know the truth *now* about the great discovery. The book is free. Ask for it.

There IS Something New in Incubators

We have taken the boldest and most important step ever taken in incubator building. See the openings into the egg chamber? They mean the saving of chicks' lives. It is the key to *right* hatching. Ventilation in the Mandy Lee is now perfect. It goes on all the time, neither above nor below, but right *at the eggs*. Every minute of the hatch the life-giving oxygen is freely passing in to the eggs and the carbonic-acid gas is passing out. And correct ventilation is just one of the great Mandy Lee features.

We Don't Guess—We Measure

The Mandy Lee is as far in advance of other incubators in heat and moisture as it is in ventilation. We do not guess at anything. The sensitive regulator controls heat to the fraction of a degree and *we measure moisture* just as accurately with the Mandy Lee Hygrometer (one sent with every incubator). You know what you are doing. *You* measure and control moisture; *you* control the hatch. The Mandy Lee is the all-season, all climate, all condition hatcher, always producing the most and the strongest chicks.

Mandy Lee Brooders give direct contact heat to the backs of the chicks. That is *real* mothering, the most important thing in poultry. Hovers are raised and lowered as weather gets warmer or cooler—heated from end to end. Chicks do not pile up and smother. Write to-day for catalog and full information.

Irrigation and Forestry

IRRIGATION INVESTIGATIONS.

In his annual report recently submitted to the President, Secretary James Wilson of the United States department of agriculture devotes much space to the irrigation investigations conducted by his department. As is well known to those interested in the subject of irrigation, the irrigation investigations have resulted in the accumulation of a vast quantity of information about the progress and practice of irrigation throughout the West. In recent years, in addition to the general investigations heretofore conducted, much attention has been given to assisting new settlers on the many public and private irrigation projects that have opened new irrigated land for occupancy.

"During the past year," says the secretary, "the office of experiment stations, while maintaining most of the old lines of work in its irrigation investigations, has endeavored to modify its plans so as to meet the demands for information on the new issues which are constantly arising.

"This is particularly true as regards the assistance which has been given to the new settlers. The task of converting desert land into productive fields is not easy under the most favorable conditions, but when the one who attempts it knows little or nothing about irrigated farming, the difficulties are greatly increased. Those in charge of irrigation investigations in the West have, therefore, devoted a considerable portion of their time to advising the newcomers as to the methods best adapted to their individual needs. This personal advice, supplemented by practical bulletins, has done much to prevent mistakes and to safeguard the settler from either partial or total failure.

"So widespread an interest has of late been created in the East regarding irrigation in the West that the department has been flooded with requests for information as to the conditions and possibilities of different districts. The series of bulletins on irrigation prepared by this department in co-operation with western state engineers and others has done much to furnish the information desired. Of this series, ten bulletins have already been published and four more are being prepared. When complete, the irrigation conditions as regards climate, soil, water supply, extent of land, crops, etc., of each state and territory in the West will be accurately described.

"In former days water for irrigation purposes was both plentiful and cheap and in attempting to use it much was wasted. In many parts of the West the old wasteful methods still prevail, although the value of water has increased many fold. The results of seepage measurements of irrigation channels obtained by the department, coupled with the high price of water rights and the rise in value of agricultural products, have induced many companies to line their main canals. As a result, many channels which formerly lost from 20 to 30 per cent of their total flow are now practically watertight. In many cases such improvements would not have been made if the attention of the managers had not been called by our engineers to the large losses sustained and the best means of preventing this waste. In other cases farmers used large amounts of water without realizing how excessive was the use until measurements were taken. When the irrigators of the San Joaquin Valley in California first began to apply water on what had been dry-farmed grain fields they frequently used over nine feet. Now about one-third of this amount is found to be ample. The water users of Greeley and neighboring districts in Colorado used to think their crops would burn up unless they had a miner's inch of water to the acre. Now they are raising crops on the same ground that are worth about four times as much with one-fourth the water formerly used. They are learning that cultivation takes the place of irrigation to a great extent.

"The demonstration farms established in former years have been maintained. These have been of great value during the past year in showing, among other things, the benefits to be derived from the use of scanty water supplies on small fields in connection with dry farming. At the Cheyenne farm during the past season, 54 bushels of oats were raised per acre with the application of only 8 inches of irrigation water, while the crop grown without irrigation was practically a failure. Alfalfa yielded 4805 pounds of hay per acre with the application of 13.3 inches, while the unirrigated field yielded only 550 pounds. Beardless barley, with the application of 9.7 inches of water, yielded 31 bushels per acre; that unirrigated and raised on summer fallowed ground yielded only 2½ bushels. At Gooding, Idaho, 8.8 tons of red clover was harvested from land which received only 19 inches of irrigation water. These results show what can be done with a limited supply of water when properly applied.

"The need of investigating the questions which arise in connection with the use of water in irrigation is so keenly felt by the people of the West that several western states are now co-operating with the department in the prosecution of these studies. For years the states of California and Utah have given dollar for dollar for the purpose of carrying on this work. The states of Idaho and Wyoming are likewise contributing considerable sums for the co-operative investigation of problems peculiar to those states. In time it is expected that many other states will enter into co-operative arrangements with the department for the investigation of irrigation problems.

"In many sections of Louisiana, Arkansas and Mississippi the ravages of the boll weevil have made the growing of cotton unprofitable and the producers are substituting other crops. Experiments with the growing of rice have proved that it can be grown there profitably. In consequence, large areas of cotton land have been planted to rice during the past season and costly failures are quite certain to result unless proper methods are followed. These farmers as a rule know but little about pumping plants, the building of levees for rice irirgation, the quantity of water to apply, and the proper time of application. It has therefore been found necessary to detail a man to this field to devote his entire time to a study of rice irrigation and to work out, if possible by experiments, better and cheaper methods than those now in vogue. A Farmers' Bulletin on the irrigation of rice for the benefit of beginners will soon be published.

"The widespread drought of the past summer throughout most of the humid region has greatly increased the interest in the irrigation of gardens, truck farms, and the demands on the one agent we have been able to detail to this work have been far greater than he could meet. The advantage of irrigation as an insurance against the long dry spells for some of the crops has been brought out in a striking manner on several farms where experiments were conducted this summer. As a result of adding both moisture and fertilizer to the soil on ex-

MOKELUMNE RIVER SCENE NEAR LODI, SAN JOAQUIN COUNTY.

perimental plats in Iowa by irrigating with sewage, the yield of beets increased one and one-half times, that of timothy was doubled, while the yield of blue grass was ten times as great as on the non-irrigated plats.

"At Neenah, Wis., it was found that irrigation prolonged the bearing season of strawberries ten days and increased the yield 50 per cent. On the same field irrigated carrots yielded 50 per cent and irrigated onions 150 per cent more than the non-irrigated crops.

"The utilization of a flowing well at Albany, Ga., in irrigating corn the past season quadrupled the yield, and as the result of an experiment conducted by this department wells are now being sunk in this district for the irrigation of corn, cotton and legumes in order to insure against droughts, to introduce scientific rotation, and to increase the profits from small farms."

The irrigation investigations maintain state headquarters in nearly every western state and territory, and in some cases, as in California, the states provide one-half of the funds used in carrying on the work. The California headquarters are in the agricultural building of the University of California at Berkeley, and information or bulletins about the work in this state may be had on application to Frank Adams, in charge, at the above address-

CALIFORNIA DRY FARMING.

In an interview with me on the subject of dry farming which appeared in the Los Angeles Times of October 20, the reporter drew somewhat heavily upon his imagination in some of his statements, and I am glad to accept the invitation of The Cultivator to give the real facts in the case.

The fact that last spring I harvested a crop of oat-hay, the best of which attained a height of six feet, was in view of the lack of rain during February and March, sufficiently interesting without lengthening its growth an additional three feet. Last year was undoubtedly a very trying year for dry farming in California. While we had heavy rains in November and December, 15 inches in Pasadena, there were no rains from January 3rd until the last of March when 2½ inches fell, with another half inch during the first ten days of April, and then no more, with the exception of a few light showers this fall, up to the present writing. The seven acres alluded to which produced three tons of hay to the acre, runs from very light to quite heavy soil and upon the latter the crop must have been nearly five tons to the acre, while on an adjoining field the crop was about one-quarter of a ton to the acre. Both fields were seeded before the heavy rain of January 3rd, but my field had been planted to melons the previous two years and to this fact I lay the heavy crop, though I plowed the land about ten inches deep and put in the crop with great care and used 130 pounds of seed to the acre, all of which had its effect. With one exception of a few years ago I have never before grown hay, but I have long wondered at the folly of farmers sowing the same land to the same crop year after year. It costs about $10 to raise a ton of hay to the acre including rent, seed, labor and baling, and if you sell your hay for $15 per ton and raise only half a ton to the acre, you are out $2.50 for every acre you put in, while if you raise three tons you are ahead $31 after paying for baling the three tons. Instead of putting in the same land to hay again this year, raise a crop of melons or pumpkins or corn, by dry farming methods, and see how big a crop of hay you will get next year. Then plow deeply, cultivate thoroughly and seed heavily. If after you have seeded the land a heavy rain comes, harrow the land lightly, even if the crop is up, and do this after every rain till the crop is high enough to shade the ground and prevent its baking after a rain. If the rains come frequently your labor is lost, but if you get a few weeks of dry weather your crop will keep on growing, and it pays to hustle as much in farming as in any other business.

Most of my experience in dry farming has been in raising melons for the Pasadena markets. I soon found that watermelons and Casaba melons grown without irrigation were far superior, both in flavor and texture to those raised with plenty of water applied during the growing season. I think this is also undoubtedly true of peaches, grapes and other fruits, and even of alfalfa. Then I take great pains in selecting my seed, saving seed only from those melons which my family agrees are especially fine, and they always demand the most promising looking Casaba for breakfast and watermelon for dinner. Then I take great pains in seeing that no melon is picked until thoroughly ripe.

The Casaba I consider the most delicious thing that grows. But nine times out of ten it is picked before it is ripe. It should be left on the vine until mellow enough to leave a dark impression under the pressure of the thumb, when it will generally easily part from the vine when rolled over.

The people have found out that the "Hayes" melon is invariably first-class and I sell only two or three of the principal stores, which handle my melons exclusively, and receive two-thirds of the retail price; which I estimate is about twice the amount received in the ordinary channels of marketing melons. Now at the middle of December I am getting $2 per dozen up, three times that price for the large ones. I don't see why this should not be done in other towns by farmers living near them. What then is the secret of raising melons by dry farming methods?

Deep plowing and thorough cultivation at the right time, going over the land, first with the cultivator, then the smoother and "plank," then the cultivator and smoother and "plank" again and again until the weeds stop growing and the ground is fine as road dust. On heavy soil two or three times the work is necessary that is required on light soil, but the results are the same on any soil. I use no fertilizer except plowing under weeds and clover, as very rich soil produces more vines than fruit. But extremely light gravelly soil is not suitable for melons.—Marshall C. Hayes, Pasadena.

UNREASONABLE HOWLING.

Inspector E. B. Heiberg of the state food department was talking about a certain restaurant in St. Paul.

"Why, it's as bad as the hotel up at—," naming a middle-sized town in the iron range.

"The landlord up there does not come out and say 'Dinner is ready,' as they do at ordinary places," he said. "He comes out with a big hand bell and rings it so it can be heard all over town.

"I was sitting in the front room one day when he came out with the bell. The ringing made the dog set up a howl.

"'Shut up!' said the traveling man to the dog, 'you don't have to eat here.'"—St. Paul Pioneer Press.

AVERY THIRTY H. P. UNDERMOUNTED

OIL-BURNING STEAM TRACTION ENGINE

FOR SALE CHEAP

This Engine is equipped with all approved time and labor-saving devices. It has been slightly used for experimental work only and is warranted to be in first-class condition.

AVERY COCKSHUTT PLOW—ten 14-inch steel bases, especially for this engine—will be sold cheap. It is brand new—has never been used. The Cockshutt Plow has won first prize at all international plowing contests for the last three years.

Both Engine and Plow will be sold below factory cost, and we will be glad to mail you description and prices. This is a real opportunity to buy a first-class outfit at big saving over the cost of inferior goods.

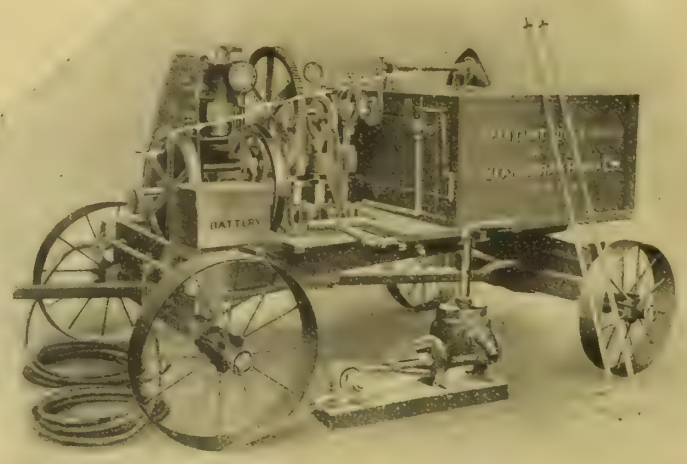
Morganhill, California.



THE BEAN GIANT POWER SPRAYER

The Most Reliable, High Pressure, Large Capacity Sprayer in the World.

The Bean Giant Power Sprayer is but 9 feet long from end to end, and but 4 feet 8 inches from the ground to the top of the tank. The Bean Giant is not top heavy and is easily hauled where most sprayers would be at a serious disadvantage—on hilly ground, for instance, or where the soil is wet or very soft.

The entire outfit weighs only from 1600 to 1800 lbs., according to equipment, which also adds to the ease of handling. The unique construction of the Bean Giant enables it to be used in the most densely planted orchards. It is very compactly built and will make very short turns.

The best standard engines are used and all Bean Giant Sprayers have the Giant Three-Cylinder Power Pump, which assures large capacity, even pressure, and a minimum of wear and strain. The cylinders are porcelain lined and are absolutely non-corrosive. Besides, they can't fill with grit and dirt—they're upright.

Don't buy a power sprayer till you've studied the Bean Giant.

SEND FOR OUR NEW CATALOG.

It describes the Bean Giant, the Bean Challenge, the Bean Pony, and all Bean power outfits, hand pumps, pump accessories, and spray materials. Sent free for your name.

Questions and Answers

THE EDITOR AND STAFF

Questions to be answered in this department should be received at this office one week before reply is expected. Write plainly on one side of the paper and sign full name and address. Unsigned communications receive no attention.

Liver Trouble.

Please tell me treatment for liver trouble in turkeys. Droppings are partly yellow, with patch of green. Is the trouble contagious?—Subscriber, Morganhill.

In turkeys this is practically incurable, and the best remedy is the hatchet where turks are badly affected. If the trouble is just beginning to show, a thorough cleansing with epsom salts, combined with cleaning and disinfecting of the houses and yards, will be beneficial. The taking of the sick turks to another run, and leaving the well ones in the infected yards, is exactly the wrong way to handle these diseases. Take the well ones to clean quarters. Absolute cleanliness, with wholesome feed, is the best preventive.

Cutting Lemon Buds.

When is the best time of year to cut orange and lemon buds to be used in March budding, and what is the best way of keeping?—H. B., Orange.

The fresher buds can be cut, the better; but, of course, it is sometimes difficult, where the sap is flowing at the March budding, to find sufficient bud wood which has not started growth. Some budders watch the orange trees closely, and, just before the young shoots begin to start from the bud, sticks are cut and buried in wet sand or moss, or, if they are to be used in a very few days, wet sacks will answer. With covering in wet sand the greatest safety is secured, because with sacks or wet straw, which is sometimes used, heating is possible, in which case the buds become worthless.

Product for Wet Land.

Will Bartlett pears grow in a sandy soil where peach and walnut trees have died from too much moisture, and what would you recommend for such land? Will cranberries and blueberries grow in swampy land where water is near the surface?—Subscriber, El Cajon.

Bartlett pears will certainly stand much more water than peaches, but if water stands near the surface we do not think they would be ideal for your situation. As to cranberries and blueberries doing well in your valley, we question it very much. We believe the dryness and heat of summer would not be best for their growth. Bartlett pears would perhaps succeed if land could be underdrained; of course, that depends entirely upon conditions.

Planting Sweet Potatoes.

At what time should sweet potatoes be planted, and where may the plants be procured? How many will be necessary to plant five acres?—Subscriber, Bakersfield.

The time of planting will depend upon your immediate locality. If mesa land, where air drainage is good and danger of late frosts at a minimum, they may be planted early, at least by the first of April, though May is not too late. Soil should be a warm, sandy loam, and plantings made on low ridges. The ordinary distance apart is 1½ by 3 feet. An acre will require nearly 1,000 plants. The retail price per 100 is 50 cents, but of course, in such quantity as is needed for setting five acres, special prices should be secured. The raising of plants and planting will be to [illegible] upon more at length in a later [illegible] of The Cultivator, in the garden [illegible] partment.

Transplanting Peach Trees.

Can peach trees that have made most a year's growth in the field, are from two to four feet high, be transplanted? Also, could blue gums four to six feet high be reset?—Subscriber, Livingston.

Either the peach or eucalyptus trees may be transplanted at that age, but we do not think the results would justify the effort. We assume that the peaches in the field you mean have planted from the nursery last spring. Nurserymen consider deciduous trees which they carry over after one season's growth after budding or grafting as of no value, and they are burned. Work with them might almost be equivalent to time thrown away.

Date Palms.

Will date palms raise good [illegible] region of Chico?—Subscriber.

It is not probable that dates will give satisfactory crops in that [illegible] though we have not heard of [illegible] being made to grow them. [illegible] orado desert and in Arizona [illegible] varieties are doing exceptionally [illegible] The so-called ornamental date palm, the Phoenix Canariensis, does not bear edible fruit. Those grown from the seeds of commercial dates may be bearing trees or more probably will not. If, however, you secure suckers from good bearing trees, it might be worth the trial in your section.

Poisoning Gophers.

What is the best way to poison pocket gophers?—Subscriber, Chico.

A small quantity of strychnine in center of whole raisin is one of the choice morsels which lay the gopher low. Split the raisin carefully, and do not scatter any of the bitter poison over the skin. Sweet potatoes, potatoes, carrots or any such roots, used as carriers for the poison, are also good. As with the raisin, do not scatter poison over the sruface, but cut the potato in pieces, say the size of a walnut or hickory nut, and slip the poison in so that it will not be tasted at first. Open the main runway, and place poisoned morsel in a few inches.

Roupy Hens for Breeders.

Will chicks hatched from stock that has had a slight touch of roup be more susceptible to the disease than if the parent stock is sound or completely cured —Z. N. D.

In general, we will say that we would not care to breed from any stock which had been affected with roup. The disease may not be hereditary, but the weakened constitutions and reduced vigor do not give promise of healthy stock. We note that you say "slight touch of roup" and "completely cured." Those two factors may completely overcome any ill effects, but, in general, reproduce only from the very healthiest.

Number of Ducks.

What is the proper number of ducks to run with one drake, Pekins and Indian Runners? What time of year does laying begin, and what is the proper feed?—Subscriber, Fresno.

The number of ducks to the drake depends upon breed and season, varying from five to twelve. With Pekins,

J pring, five is the proper number; r, in early summer, seven or eight ould be allowed. With Indian Runners, six or seven is the usual number, though some breeders increase to welve. They begin laying early in March, and will continue until early sometimes mid summer, according o care. The following ration is recmmended by "Ducks and Geese," pubgrea by Reliable Poultry Journal: of g e fed every morning and evenm Five measures corn chop, five measures bran, two measures midper one and one-half measures cent ap, three measures boiled veg- "T three measures cut green Alb per cent sand."

past

nard Planting.

I have an orchard, seven arces of same being set out. Three acres was et one year ago to apricots and walir , the walnuts being cut back on count of frost or something, mak- t rather unhealthy-looking trees. The ots are fine. But the old part of orchard, seven acres, was set wenty feet apart, and the entire orchard is regular. The new three acres was set thirty feet apart, which does not conform to the old. Taking into consideration the kind of walnuts have, what disposition would you e of the three-acre piece? There six rows—three rows apricots rty-one trees each), and three rows nuts.—M. L. T., Hemet.

nia

bulle walnuts are not strong and ma y after their first year's growth, Ada uld replace with stock that is. dress- ne from the inquiry that the d apricots were set in alter- s, with the expectation of CAL g out the apricots and leavIn walnuts sixty feet apart. If su is the desire, that would be a ood distance apart for them. If the inquirer wishes to know as to making the three acres conform to the seven, we are unable to answer, that being a matter for his own taste to decide. Of course, it would be impossible to grow walnuts as one would peaches or apricots, twenty or twenty-four feet apart. If a uniform orchard is desired, then trees of only one variety would be preferred. It would be unwise to attempt to lift the apricots and reset in conformity with the older orchard, so that the only question would be as to wiping out the newer setting and replacing entirely with other trees. If the walnuts and apricots have grown thriftily, this would occasion a loss of one year's growth.

Tincture of Aconite.

For indigestion, or almost any disease that fowls are heir to, I have found aconite a wonderful remedy. One teaspoonful to one gallon of water, put it where the fowls can have all they want. If the fowl is very sick, I take about three tablespoons of water with three or four drops of aconite, wet a piece of bread in this, and force it down the throat, pouring the water that is left down the throat. May have to repeat the dose next day.—T. F. Burrows, Tulare.

Veterinary

Answers in this column by Dr. Fred G. Matthews, are without charge. For immediate mail answer remit $1.00. In writing questions give full symptoms or particulars of injury of animal.

Contagious Eye Disease.

Twenty head of heifers, fed alfalfa and middlings along with their pasture, have sore eyes. Tears flow freely, and the eyes are nearly closed, but examinations reveal nothing in the eyes. Some have recovered, while others are contracting the trouble. Is there a disease, or do you think grass has struck the eyeball while they were feeding?—Subscriber, San Jose.

Grass spears would not affect all your young cattle—both eyes alike—in such systematic disorder. This is an infectious form of catarrh of young cattle. Old cows are rarely afflicted. From your description, the disease appears to be running a mild course, and will soon disappear. However, it would be well to see that your cattle have pure water, wholesome food, and clean, comfortable quarters, especially at night, and to avoid the spread of the disease to your neighbors' herds. —F. G. M.

Bladder Trouble.

For about one week my horse has been urinating too often—half a dozen times in a half day. His appetite is good. The food given him consists of grain hay and Egyptian corn twice, and alfalfa once a day.—Subscriber, Turlock.

Try leaving off the alfalfa first, and then each of the other foods, to determine if either is responsible for the trouble. Have your druggist prepare sixteen powders, each containing potassium iodide half drachm, gallic acid one drachm, and powdered belladonna two drachms, and give one powder in ground feed twice daily.

OPPORTUNITY'S MISTAKE.

"This is the opportunity of a lifetime, madam," declared the smooth-tongued canvasser as he stood at the door.

"Seems to me I've heard that before," thought the housewife.

"Opportunity knocks at every one's door—but only once," continued the caller.

"That's where you're mistaken, young feller," snapped the woman as she reached behind her. "Opportunity has knocked at my door eight times this week so far. I'm out four dollars and ten cents, an' nothin' to show fer it. Jest in case he should knock again I be'n savin' this kettle o' hot suds—"

But Opportunity departed hurriedly. —T. L. Holiday in Woman's Home Companion.

"Especially do I think that the farmers' wives should be assisted and helped in every way possible. I want to see farm life so arranged that there shall not be a better outlook for the farmer than for the farmer's wife. While he is equipping his place with machinery for outside work, he shouldn't forget the new devices for inside work. Don't forget the modern machinery that makes woman's life easier on the farm. We hear much about women's rights. Decent men should be thinking about women's rights all the time."—Theodore Roosevelt.

Irrigators on the west side of the San Joaquin valley who hoped for the formation of a Wright Irrigation District, to cover many thousand acres of land, find they will be oposed by Henry Miller, who owns much land within the boundaries of the district.

Mr. Farmer---

Prepare now to give your Soil a Spring Tonic.

A change of food is essential to health of man—so is some form of fertilizer essential to the productiveness of your soil.

Our little booklet, "Farmers' Friend," will explain to you the good qualities of our fertilizer and tell you what it has done for others. Write for it today—it is free.

Crop Specialist Tells

How To Make Your Land Pay

$500 TO 1200 Per Acre

That may sound like a story—but I am here to tell, to show and to prove that a profit of from $500 to $1,200 per acre is within the reach of every farmer or grower in the country. I have made this remarkable record on my farms for several years—other farmers who have adopted my methods are also succeeding—the same success is within your reach. The secret of this wonderful profit is scientific and intensive farming, special preparation of soil and the growing of special crops.

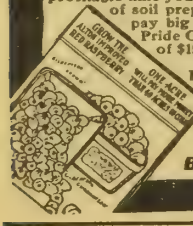
Write For My Two Free Books

Book No. 1 is my intensive farming book, not a catalog, published to sell for 50c; send and get it now free; tells of my experiments and experience for the last 32 years. It has taken 32 years to write and to complete it. If you will at least spend 32 minutes reading it it will prove to be the most profitable time you ever spent. This book explains my special method of soil preparation, how to rotate crops, how to make your land pay big profits as I have done by growing my Grandpa's Pride Globe Onions which have produced an average profit of $15,000 on 40 acres and other special crops.

Book No. 2 gives the history of the Alton Improved Red Raspberry which has produced an average profit of $1,200 per acre on account of its remarkable size, flavor, long fruiting season and vitality.

Write for my books today, they are free and will interest the man who is looking for big profits.

A. O. GILBERTSON, CROP SPECIALIST,
Box 619 Mason City, Iowa.



I Have Farmed For 32 Years

During this time I have experimented, my one aim was to produce special crops that would be out of the ordinary in quality and profit. One of the most successful experiments was with raspberries. Instead of growing the ordinary variety and taking an ordinary profit I propagated a special variety now known as the Alton Improved Red Raspberry that has stood the winters of Northern Minnesota, North and South Dakota and even as far north as Canada, without the least winter protection. The Berry is especially remarkable for its size and delicious flavor as well as for its long fruiting season, which on an average extends over a period of three months. If you only have a city lot or if you have a farm investigate this wonderful, large, delicious berry now.

EUCALYPTUS TREES

Large quantity, extra quality to select from. **ORANGE and LEMON TREES,** A. 1 quality, A large assortment of **PALMS.** Orange Seed Bed Stock, Sour and Sweet.

Timely Ranch Suggestions

ALFALFA EXPERIENCE.

By C. E. Lillibridge, Corona.

I enjoy reading reports of the experience of alfalfa growers, and possibly your readers will like to know how we grow alfalfa at Corona. I own forty acres, and pump 276 inches of water, at a cost of twenty cents per hour, fourteen feet from the surface. I pump through twelve-inch steel pressure pipe underground, and use ten-inch surface irrigating pipe to distribute.

My alfalfa has been seeded five years, and I have no foul grasses or ditches. I take out Bermuda grass with a delving fork, and burn every joint whenever it shows up. It is practically all clean, and I keep it so. I fertilize in December, and spring-tooth harrow it both ways in January or February. I use stable manure, the same as for corn in the East. I use cow manure, which I buy at two cents per foot at the dairy. I bale ten tons to the acre each year, and sell 100 tons during the season to keep up all expenses, and store 300 tons for winter prices. I bought ninety-two tons this season at $10, and have 400 tons holding for the winter price, and in this way I get the storage man's profit, and net $3,000 per year on an average. My land is not for sale at any price, as I am satisfied with this.

I hire all hay baled in the field, and I mow and rake my own hay, and bunch with a rake. I never use a fork. I also cart or haul into the barn all my hay, and I keep only one man to do the irrigating and help put baled hay in the barn. It takes twelve days to irrigate once over, and then I usually put in five to ten days going over any spots that look as if more water would do any good.

If anyone has a better plan of growing alfalfa hay, I would like to learn it, as we can always learn in the curing and in growing the most tons to the acre. I cut six cuttings, and let my hay mature well, or cut when one-quarter in bloom, but, owing to my land being so thoroughly soaked, the leaves all remain on, and I handle all hay while damp with dew, which helps in keeping on all leaves. Then I turn over all hay with a rake each morning, from the time it is bunched until it is baled, before the sun colors it, thus keeping it all damp and of a perfectly green color. The sun shining on hay with dew on it is what colors it. If turned over before the sun strikes it each morning, which takes about one hour to ten acres, it keeps perfectly green.

ERADICATE JOHNSON GRASS IN SUMMER.

By Prof. Elmore Chase, Fair Oaks, Sacramento County.

The problem of eradicating Johnson grass from the roadsides is a very difficult one, because of the great variety of soil conditions and the number of types of root stock development. But to grub out Johnson grass at this season of the year is a waste of time and money. In order to make it effective, the grubbing must be very thorough. This would require, in mellow soil, digging from one to three feet deep and sometimes deeper. Johnson grass can be eradicated by this method but the process must be repeated the second year, since it is well nigh impossible to remove all the root stocks. Mr. J. S. Cates, scientific assistant of the Bureau of Plant Industry at Washington, has given several years of careful study to the root stock habits of this grass, and has fully demonstrated that this pest can be brought under control in one year's thorough cultivation under ordinary field and meadow conditions, and this is done with comparatively little expense. This method applied to your conditions would be to allow the soil to remain undisturbed this fall. Where the Johnson grass has grown the past summer, the ground is well stocked with rootstock. Every one of these will begin to grow in the spring season and continue to do so as late as August, if the soil and moisture conditions are favorable. If now this grass is not allowed to make much growth beyond the blossoming period, in fact, it is better not to allow it to bloom, the formation of rootstock for next year's crop, if they grow at all, will be confined near the surface. The most efficient way of preventing this growth where the soil conditions are favorable, is to run a weed cutter just below the surface of the ground so as to cut off the crown of grass. This is about three or four inches below the surface. This should not be done till the grass is heading out. By going over the ground twice, possibly three times during the season, there will be but few root stocks for the next years' growth, but this cannot be done under all conditions. Other weeds, shrubbery, or rocky soil may prevent the use of a weed cutter. A good instrument for this work in arable land is to remove the plows from a two-gang plow and substitute two V-shaped weed cutters made of steel and constructed to fit the plow, and with a good strong team some very difficult soil can be thus treated. Other methods may be employed according to the soil conditions. The essential thing is to sever the crown of grass above ground from the root stock just below the crown. A large amount of hand work will have to be done. A man with a good strong hoe can clean up a large patch of ground in a day. The root stocks near the surface will send up tufts of grass earlier in the season. Later, root stocks from lower depths will send up tufts of grass and this will continue until August as above mentioned. By allowing the grass to head out, the root stocks in the soil will be exhausted and not send up shoots again, and if they are severed before it blooms, no new growth will be formed for next year. Let no one be discouraged because after once cutting, more grass comes up the first year. Of course there will be all stages of growth of the grass at each cutting, but it is the blossoming bunches that will be destroyed each time. Later in the season, new root stocks are formed even if the grass is not allowed to head out. If land is pastured several years enough short root stocks will be formed to continue the existence of the plant. If road sides could be pastured with sheep or goats one season and then in the fall a shallow plowing will almost entirely destroy the new root stocks which seldom extend more than three or four inches. Of course the grass will appear occasionally the third or

fourth year after such treatment, but it will be under control by careful cultivation.

Disturbing the root stocks by plowing is equivalent to planting. The more the root stocks are broken the greater will be the number of tufts of grass. By cutting a potato into many pieces, more vines will grow.

How Johnson Grass Grows.

A careful distinction should be made between roots and root stocks of our noxious weeds. One species of the morning glory is propagating by roots, and another by root stocks. If one thinks of the root stocks of Johnson grass as a tuber or a potato, he will understand readily the method of destroying this pest by preventing the growth above ground. Every one knows that if potato vines are cut at the surface about the time they bloom, no new potatoes may be expected. The same is true in regard to the new root stocks of the Johnson grass, though the latter is more difficult to destroy.

As an illustration we may suppose a long root stock be formed beneath the ground from one to three feet in mellow soil. During the spring many buds will start from the joints, forming a new root stock reaching up to the surface of the ground. On reaching the surface a vigorous growth of grass is sent up. This continues to grow rapidly until the flower stalk is well begun and ready to bloom. At this point a new white shoot at the crown starts downward, forming a new system of root stock for the next year. These are very numerous, and if the grass is allowed to mature, the ground will be well stocked. The old root in the ground is called the primary root stock. That which comes up from the primary root stock and forms the tuft of grass is called the secondary root stock, and the third which descends into the ground is called the tertiary root stock. The primary always dies every year, but the secondary and tertiary become the primaries for next year.

It is evident, if the tertiary root stock has but a shallow growth, that the secondaries for next year will be nearly eliminated. A root stock two or three feet in the ground furnishes a large amount of secondary rootstock. These also send out other secondaries as they come up, thus a large mass of stock fills the soil for the next year's growth. Thus by preventing the growth above ground, either by frequent cutting with scythe, or pasturing, the rootstocks will be formed near the surface. Then by shallow plowing for winter fallow, or by spring plowing for either summer fallow or a cultivated crop, this pest will be brought under control in one year. If any of the grass is allowed to go to seed, the work has to be done over again.

This method of eradicating this pest has been employed in this county and in every case where labor could be had and faithful work has been done the success has been complete.

There is no reason why California can not get rid of this pest in a short time. It will take faithful work. When the right stage of growth is reached, then no delay in doing the work can be had without loss. The matter of seeds is not difficult to control, as these are easily destroyed as any ordinary weed seed, before the root stock system is formed. The requirement not to allow seed to form is to prevent the dissemination of the plant and to keep back new growth of rootstock.

Mr. J. S. Cates has sent to my office a number of bulletins for distribution. By the rules of distributing these bulletins only one can be secured by an applicant. In order to facilitate the distribution in this state I can send these to any one on application by simply sending postage. Each Horticultural Commissioner should have a copy or more for the use of his county.

You know it is not an easy matter for one to read a bulletin and fully understand its application. One must investigate for himself. I have often been compelled to dig up the grass and show the farmer what the grass is doing and show him how to prevent these new points that are seen on each bunch of grass about the time it is ready to bloom. Once convinced, and the work is done.

If meadow land is once planted to alfalfa, the whole problem is solved if the alfalfa is cut before the Johnson grass heads out, and this is generally so far behind the alfalfa that it is readily done.

VALUE OF THE GARDEN.

The Farm, Stock and Home suggests that possibly some of the cityward movement of the farmers' sons could be traced in a measure to the lack of a home vegetable garden. A continual round of pork, beans, potatoes and bread, or any other unvaried, monotonous fare, seldom broken by green, succulent and delicious dishes from the garden, is not conducive to a very happy farm life. Meals, instead of being made merely a means of satisfying hunger—often to be approached without relish, and to be partaken of because of necessity, which is altogether too often the case on the farm—can be made a source of infinite pleasure. The farmer's wife is, of course, an important factor in making meals such a source of pleasure; but she is by no means the only factor. How many women there are who could say to their husbands: "Let me have more things to cook, and I will prepare you better meals."

Perhaps the family resources do not permit the purchase of everything that is desired; but how often a continuous supply of fresh vegetables would help to vary an otherwise monotonous meal or a mere "fill-up," and add to it those qualities which make it eminently more to be desired! The more limited the family resources are, the greater is the need of such a supply of vegetables.

It is impossible to imagine how any farmer who gives this matter but a moment's thought, and who cares at all for the health of the family and the happiness of the home life, could be without a splendid home vegetable garden. Even if it meant less profit from field operations, the farmer should not go without a vegetable garden, because of the innumerable ways in which it adds to the pleasure of home life. But it need not be done at a decrease of profit.

A GIRL'S ESSAY ON BOYS.

"Boys are men that have not got as big as their papas, and girls are women that will be ladies by and by. When God looked at Adam he said to himself, Well, I think I can do better if I try again, and he made Eve. Boys are a trouble. They wear out everything but soap. If I had my way the world would be girls and the rest dolls. My papa is so nice that I think he must have been a little girl when he was a little boy. Man was made, and on the seventh day he rested. Woman was made, and she has never rested since."

WRITE FOR CATALOGUE AND PRICES

Trees: Book orders now for the following standards.

Peaches: Tuscan, Orange, Phillips, Levi, Foster, Triumph, St. John, Early Crawford, Elberta, Muir, Lovell, Fay-Elberta, and Salway.

Peaches have paid growers more profits in the last 25 years than any other fruit.

Apples: Alexander, Red Astrachan, Gravenstein, White Astrachan, Jonathan, Rome Beauty, Spitzenburg, Bellflower, Newton Pippin, Grimes Golden Pippin, Ortley, McIntosh Red, Winesap, Wagner, Winter Banana, Arkansas Black and many others.

Get in your orders now for Gravenstein, Jonathan, Spitzenburg, Yellow Newton Pippin, White and Red Astrachan, Alexander. They always sell out first.

Cherries: Black Tartarian, Bing, Black Oregon, Black Republican, Royal Ann, Lambert.

Cherries are great money makers. The above varieties always sell out early.

FARM LANDS FOR SALE.

For Sale—By owner, good farm land, $50 per acre, in Merced County, 9 miles from Merced and ½ mile from station on S. P. and 4 miles from La Grande on Santa Fe. This land is a rich, sediment soil, situated in the Artesian Belt and an abundance of water is thus assured. Is level and all under cultivation. No alkali, and is suitable for figs, corn, alfalfa, beans, and all farm crops. Will subdivide in lots from 40 to 1000 acres. This land is very cheap at the price. In fact, it is only one-half the price of other land in same locality. For further particulars call or address Paxton, 612 Lankershim Bldg., Los Angeles.

For Sale—A 20-acre farm for $20 cash and $20 a month; possession now; $90 to $125 per acre; your crops pay for the land. Rich, level land for alfalfa, oranges, almonds, grapes, cows, chickens; abundance of ditch water, for irrigation, for $1 an acre a year. Where else can you get this? In Oakdale Colony, near good town and railroad station, climate delightful. T. Wiesendanger, 207 S. Broadway, Los Angeles, Cal.

RANCHES.
RANCHES.

Want any bargain poultry, stock, grain, alfalfa, orchard, grove, dairy, nursery, vineyard around So. California. Large and small for sale or exchange. Parrish Barker, 207 Union Trust Bldg., Los Angeles.

RANCHES.

Address Wayne Dinsmore, Secretary, Union Stock Yards, Chicago, Ill.

BUSINESS METHODS IN FARMING.

Farming is a business, and when conducted on a proper basis is one of the most profitable businesses in which a man can engage.

As a rule, however, the farmer does not run his farm along the strictly business lines of the manufacturer and merchant, and he is the loser because of it.

It is the custom among many of our farmers to gauge their profits by the size of the crops and the price they bring alone, rarely taking into account the individual expense attached to producing the crops. Through this system, or lack of system rather, the farmer often finds himself poorer at the close of the season than at the start, and he wonders why, in spite of good crops and fair prices he doesn't prosper.

There are many farmers working along year after year, depending largely upon the weather and market prices for a successful season, who could increase their yield of crops, reduce working expenses, and add greatly to their profits by adopting improved time and labor-saving Planet Jr. tools in their work.

The well-known Planet Jr. farm and garden tools are the greatest time and labor-saving farm implements ever invented. They frequently do six men's work and enable the farmer to get larger and better crops with half the labor and expense.

These implements are the invention of Samuel L. Allen, himself a practical farmer, and they are adapted to every variety of farm and garden work.

Every farmer who is desirous of improving his farm and garden and adding to his profits should procure the Planet Jr. catalogue which will be sent upon request by addressing S. L. Allen & Co., Philadelphia, Pa., manufacturers of Planet Jr. tools.

General Household Notes

'IKE HIS MOTHER USED TO MAKE.

was born in Indiany," says a stranger lank and slim,
As us fellers in the restaurant was kind o' guyin' him,
And Uncle Jake was slidin' him another punkin pie
extry cup o' coffee, with a twinkle in his eye.
was born in Indiany—more'n forty years ago—
An' I ain't been back in twenty—and I'm workin' back'ards slow;
But I've et in ever' restaurant 'twixt here and Santa Fee,
nd I want to state this coffee tastes gittin' home to me!

as out another, Daddy," says the feller, warmin' up,
speakin' 'crost a saucerful, as Uncle uk his cup.
n I seed yer sign out yander," he went on to Uncle Jake—
ome in and git some coffee like yer mother used to make'—
ght of my old mother and the osey County farm,
a little kid ag'in, a-hangin' on her arm
s she set the pot a-bilin', broke the eggs and poured 'em in,"
And the feller kind o' halted, with a tremble in his chin.

And Uncle Jake he fetched the feller's coffee back, and stood
As solemn, fer a minute, as a undertaker would;
Then he sort o' turned and tiptoed to'rds the kitchen door—and nex'
Here comes his old wife out with him, a-rubbin' of her specs—
And she rushes for the stranger, and she hollers out: "It's him!
Thank God, we've met him comin'! Don't you know your mother, Jim?"
And the feller, as he grabbed her, says: "You bet I hain't forgot—
But," wipin' of his eyes, says he, "yer coffee's mighty hot!"

—James Whitcomb Riley.

SO LONG AS LIFE SHALL LAST.

It is years ago that I saw it, but I can still remember that it was near the top of the left hand column on a certain right hand page of some magazine that my eyes first fell upon the words: "The more I see of people, the fonder I am of dogs." Whether it was quoted, or whether the writer was giving utterance to a saying of his own, I have no idea. It did not mean necessarily that the man who said it originally was no lover of his kind. It does not mean that the man who still quotes it as an expression of his own thought is indifferent to the relations that bind him to his fellows. But he who has known the love and companionship of a dog, and found in that loyal friend something that has never failed him, disappointed him, or deceived him, wishes that he could say as much of many of the men and women he has met. That genial humorist who has just left us, once said: "If you pick up a starving dog and make him prosperous he will not bite you. This is the principal difference between a man and a dog." The saying reminds you of a remark made in one of his speeches by Sir Robert Peel with reference to another who had bitterly opposed him: "I am at a loss, Sir, to conceive what can be the cause of the strong hostility to me which the honorable gentleman exhibits, I have never conferred on him an obligation."

To have one friend who meets all your moods with the same unchanging affection, who makes no sign of complaint no matter whether you meet him with glad or heavy heart, who looks up out of confident eyes that seem to say, "I am here, ready to go with you if you want to go; ready to stay with you if you want to stay; talk to me, or sit in silence, only count upon me always,"—to have one such friend, even though he does not speak your language, or ever call you by name, is to enter into a relationship with far more influence upon your life than a stranger to such an experience might ever guess. Perhaps we must call him a brute, this animal with four legs instead of two, but to know him, to trust and love him, is to grow more human rather than less. It is often to learn from him lessons of patience, of forgiveness, of gratitude. They are not few who after some moment of forgetfulness, or of illtemper of which that unresenting companion has made them ashamed, have taken the patient face in their hands and said: "Dear old friend, Forgive me! I hurt you; I am sorry. If only I could blot out injury and hide away in oblivion ingratitude with your splendid magnanimity! At least I should call it that I found it in a human friend."

There are multitudes of people who have no more capacity for appreciating a dog than others have for feeling the beauty of a noble piece of music or perceiving the glory of a great painting. Both are to be pitied. Each goes through life missing something that has in it, if he only knew it, much which could refine and enrich his soul. Men who know dogs, and have loved them, sharing with them many a sorrow and many a joy, are perfectly honest when they say that there are times when it would cost them far more to lose the companionship of their dog than that of a whole host of some of the people with whom they have often had to associate.

How long the dog has been man's trusted friend we have no means of knowing. Travel back as far as we will through the literature of the race, we find him always manifesting those same traits that win for him today his place in our hearts and in our homes. It is a far-off time of which Homer sings in the Odyssey, but how many of us feel the pathos of the picture he draws for us when, after the many years of great Ulysses' wanderings he returns at last a stranger, in the guise of a vagabond, unrecognized by those who once had known him best. The story runs:

A dog was lying near,
And lifted up his head and pricked his ears.
'Twas Argus, which the much enduring man
Ulysses long before had reared, but left
Untried, when for the hallowed town of Troy
He sailed . . . And he saw
Ulysses drawing near, he wagged his tail
And dropped his ears, but found that he could come
No nearer to his master. Seeing this
Ulysses wiped away a tear unmarked
By the good swineherd.

Neglect and age had done their work upon this loyal friend. He was too old and weak even to crawl to his master's feet, but he had not forgotten, and when Ulysses
Passed through to where the illustrious suitors sat

. . . over Argus the black night of death
Came suddenly as soon as he had seen
Ulysses, absent now for twenty years.

Shall we outgrow him, this age-long friend? Shall we become so highly civilized at last as no longer to need his companionship, to prize his affection, to appreciate his devotion, to learn from him some deeper meaning in that word, fidelity? It may be. But generations will come and generations will go, how many of them no man can tell, before the race to which we belong will turn from its doors and shut away from its friendships this unfailing friend who has been willing down all the centuries to follow his human master through want and shame and sin even to the grave.—Sunday Globe.

ASPARAGUS RECIPES.

Asparagus Salad.

Tie the asparagus in bunches, heads all one way, and cook three-quarters of an hour in salted water. Drain, and have quite cold before using. Make a dressing with a teaspoon of mustard, a teaspoon of onion juice, half a teaspoon salt, a little white pepper, six tablespoons olive oil, three tablespoons lemon juice or vinegar. Add a little oil to the dry ingredients and rub smooth, add the rest of the oil, and lastly the lemon juice, and beat until creamy. Pour over the cold asparagus just before serving.

Plain French Dressing.

Plain French dressing with the cold asparagus served on lettuce leaves with slices of hard-boiled eggs gives another most acceptable salad.

Baked Asparagus With Eggs.

Break into inch lengths, and boil until tender in salted water. Turn into a buttered baking dish with a cup of nice cream sauce, break the required number of eggs over the top, dot with butter, dust with salt and white pepper, and bake until the eggs set.

Asparagus With Cheese.

Boil in the usual way, drain, and put into a buttered baking dish in layers with grated cheese between. Cover the top with buttered crumbs, another layer of cheese, and bake ten minutes in a hot oven.

Cream of Asparagus Soup.

From a quart of asparagus break off an inch of the tips. Break the remainder of the stalks into inch lengths, and if the bottoms do not snap easily put them on to boil a half hour before the tender part is added. Use just enough salted water to cover, and when tender rub through a colander or sieve. Add one pint each of veal or chicken stock and milk, or without the stock a quart of milk. Rub a tablespoon flour into butter the size of an egg, and add to the soup with white pepper and salt to season. Stir until it thickens, add the tips which have been cut into bits and cook separately, and pour over dice of toasted bread or serve plain as preferred.

Asparagus With Scrambled Eggs.

Beat six eggs without separating, add six tablespoons milk, salt to season, and beat again. Add an equal quantity of cold boiled asparagus cut into small pieces. Heat two tablespoons butter in a spider, turn in the asparagus and eggs and scramble until thick and creamy.

Asparagus Patties.

Cut a quart of asparagus into small pieces and cook in salted water until tender. Add a white sauce made with two tablespoons butter, one of flour, one-half teaspoon salt, pinch of white pepper and one cup of milk. Cut two slices of bread, remove the crusts and scoop out the centers. Toast a light brown over the coals or in the oven, fill with asparagus and serve hot. Or prepare cases by lining deep gem or patty pans with a rather short crust, cutting lids of crust for the top and baking on a separate pan. When both are baked, fill with the hot asparagus, lay on the lids, and serve immediately.

Asparagus Fritters.

Make a batter with two beaten eggs, a tablespoon butter, one cup of flour, a little baking powder and salt, and enough milk to make a drop batter. Add cold cooked asparagus, cut in small pieces, to the batter, and fry in deep fat.

Creamed Asparagus on Toast.

This is a palatable way of using left-over asparagus for breakfast or supper. Melt two tablespoons butter, add one of flour, stir smooth, add salt, white pepper and celery salt to season, and one pint of milk. Stir until it thickens, and add an equal amount of cooked asparagus cut into bits. Spread over thin slices of freshly toasted bread and serve at once.

HOMELY HINTS.

Orange peel burned in a room will remove any close, foul odor, and is especially refreshing in the sick room. Place the peel in a shallow pan, and burn for several minutes.

Stains in table linen can be removed by plunging into clear, boiling water. Soap will only set the stain.

Light kid-gloves can be cleaned by gently rubbing with a cloth dampened in milk, and afterward dried with a dry, clean cloth.

Tennis flannel makes excellent broom bags. If dipped in kerosene oil and dried they will remove all lint and dirt from the hardwood floors and leave a gloss that can be obtained in no other way.

Machine oil stains should be rubbed with lard and let stand several hours and then washed in soapy water.

To remove a scorch, wet the spot, rub with soap, and bleach in the sun.

When the eyes ache, after reading, writing or sewing, especially in the evening, it is a sure sign that they need rest. Work should be discontinued immediately, and the eyes given a hot bath, taking care not to go into a draft, or cold air, until they have cooled.

Dish cloths should be kept scrupulously clean by washing thoroughly in soap and water, well rinsed and hung in the air, after using.

An ordinary brick is excellent for an iron-stand, and if heated before using, the irons will keep hot much longer than with the common iron stand.

NERVOUS HEADACHES.

"Nervous headaches occur in hysterical or neurasthenic individuals and those suffering from overwork or worry," says Dr. Jean Williams, in the Woman's Home Companion for December. "In this class might also be mentioned headaches due to eye-strain. The error of vision may be so slight that the patient is not conscious of any impairment of her sight, but the constant effort to counteract is sapping her nervous energy. When frequent headaches occur, it is important to have the vision carefully tested by a competent eye specialist. No further search for a cause may be necessary. Disease of the ear, a de-

EUCALYPTUS

The best that 40 years experience can produce, being grown slowly, in the cool atmosphere of the coast, are more hardy and more vigorous than those grown in the hot interior of the State.
Correspondence Invited.
W. A. T. STRATTON, Petaluma, Cal.

viated septum in the nose; adenoids; enlarged tonsils, and other abnormalities of the nose and throat, are often responsible for persistent headaches that resist treatment. In all cases these possilbe conditions must be considered and, one by one, eliminated. Persistent headaches require careful study by a careful, competent physician, and painstaking observance of the advice and directions he gives."

"TIMES IS CHANGED."

"Yes, siree, Bill; times is changed since you an' me was doin' our courtin'," said Adoniram Clover, with a note of sadness in his voice, to old Andy Clover, who had come over to "set a spell."

"When we was doin' our courtin', Andy, a gal thought she was bein' treated right harnsom if a feller bought her ten cents' wuth o' pepmints once in a while, an' if he tuk her to any doin's in town, she didn't expect him to go down into his jeans to the tune of a dollar or two for ice cream an' sody water, an' candy at fo'ty cents a paound. My son Si tuk his ducksy-daddle to the band concert in town yistiday, an' there wa'n't a quarter left of a dollar bill he struck me fer, time he got home. Beats all, the way young folks throw the money away nowadays. I tell ye, times is changed mightily since we was boys, an' the Lawd only knows what the end will be, with a feller layin' out seventy-five cents on a gal in one day!" —St. Louis Republic.

MEASURE OF BEAUTY.

Women are wont to say that they dress for the men. I believe they do; also for themselves; also for other women, says Erman J. Ridgeway, in The Delineator for August. I don't believe one man in a thousand can appreciate an elaborate gown. Most men, I think, like simpler effects. A gaudily overdressed woman makes her escort painfully self-conscious, if he be a gentleman. But all men can and do appreciate the ensemble of a beautiful face and a beautiful figure beautifully gowned. And the simpler the gown, the greater the appreciation. The best dressers realize this. I heard of one recently whose parting injunction to her tailor was: "Spare no expense to make it simple."

Why is it that trained nurses are so attractive? I never saw an unattractive one, and some of them are "a joy forever." Is it health? Their study has taught them how to take care of themselves. Is it their immaculate costumes? Why shouldn't everybody be aseptically clean? Is it their mission which appeals to our sentiment? Why shouldn't everybody have a mission? After all, isn't that our real measure of beauty?

PINEAPPLE CONFECTIONS.

Pineapple Bonbons.

Drain the contents of a can of sliced pineapple, reserving the juice for sherbet or pudding sauce. Cut the rounds of pineapple into pieces of even size, about one-half an inch at the outer edge. Place on a plate so that they do not touch, and dry in the gentle heat of an open oven. Boil sugar to the "soft ball" stage, and beat to a fondant. Shape the fondant over the pieces of pineapple, decorating the white bonbons with bits of candied cherries, violets or angelica.

Pineapple Glace.

Prepare the pineapple as for the other confections, taking care that the surface of the pieces is quite dry, as this is essential to success. Boil sugar without stirring until it spins a brittle thread, and pour carefully into a cup or bowl which stands in a pan of very hot water. Dip the pieces of pineapple very carefully into the hot candy, and cool on lightly buttered plates. Like all other glaces, this can be made only in crisp, sharp weather, as very moderate heat or moisture will make the surface sticky.

FUN FOR EVENING GUESTS.

Each one in the company must be supplied with paper and pencil and then you ask all together to suggest ten letters of the alphabet, which are then to be written down at the head of each one's sheet of paper in the order in which they were suggested.

Now, the players must exercise their wits to make up a telegram of ten words beginning with the letters in the order given.

After ten minutes or so call "Time's up," and gather up the papers. Display a prize for the one to be adjudged as best and then read the telegrams aloud. Let the company decide which is best.

Here are examples:

Suppose the letters were A, L, W, K, B. E. T. O. G. H.

One telegram: Ailce Lane Will Know By Evening That Oscar Gambles Horribly.

Another telegram: Another Lad Will Kiss Before Edith Thinks Of Going Home.

Lots of fun in this game. Try it.

TWO BATCHES OF BISCUITS.

At the breakfast the biscuits were rather harder than they should have been, and Jones growled out:

"I wish I were an ostrich maybe I could eat these biscuits and live afterward."

"I wish you were," said Mrs. Jones. "Maybe then I'd get a few feathers for my hat."

This reminds us of another story. A young husband came home and found his bride of a few weeks in tears. "What's the matter, my dear?" he asked. "Oh," she said, "the dog has eaten the biscuit!" "Why, never mind, my dear," he replied soothingly, "I'll get you another dog."

ORANGE MARMALADE.

Slice very thin twelve oranges and three or four lemons, using the entire fruit, but removing all seeds. To every pound of fruit add one quart of water. Set away for twenty-four hours. Boil the fruit in the same water till tender, then to each pound of the boiled fruit add one and one-half pounds of sugar. Boil till transparent, about forty minutes. It will be thin at first, but will jelly nicely when thoroughly cold.

A GOOD SHAMPOO.

There is no better shampoo than that made by beating a raw egg into a sponful of castile soap jelly. The latter is made by dissolving soap (to any quantity) in boiling water, letting the mixture stand where it will keep hot, but not cook, until the soap is dissolved. When cold it will be thick. This keeps indefinitely, until the egg is put in. A tablespoonful of water may be added to each egg and spoonful of soap, and the mixture is massaged over the scalp and hair before washing in clear water.

SAUCE FOR THE HEN.

Mother—Alice, it is bed time. All the little chickens have gone to bed.

Alice—Yes, Mamma, and so has the hen.—Harper's Bazaar.

Scott, Magner & Miller say:

Arrivals of hay for the week have been 2,400 tons. The receipts for the last two weeks have, therefore, been somewhat lighter than usual.

There is somewhat of uneasiness felt in certain sections where no rain has fallen, and many of the holders of hay in those sections are adverse to disposing of their interests until some change is marked in the situation.

There is some inquiry in the interior sections for alfalfa hay for dairy purposes, and some movement has taken place in this article on that account. There is also some alfalfa being moved this week for shipment to the north, but not to any great extent. However, under these conditions alfalfa is firm and shows an undercurrent of strength.

A strong advance in prices is noted.

We quote the wholesale prices in round lots on today's market as follows, viz.:

Fancy wheat	13.50@14.00
No. 1 wheat or wh and oat	11.50@13.00
No. 2 wheat or wh and oat	10.00@11.00
Choice tame oat	12.00@12.50
Other tame oat	9.00@11.00
Wild oat	8.00@10.50
Stock hay	6.00@7.00
Alfalfa, ton	9.00@12.00
Straw	40@50

Grain.

Wheat, No. 1	1.42½@1.50
Barley, fancy	1.12½@1.15
Barley, good to choice	1.07½@1.10
Barley, poor to fair	1.00@1.05
Oats, white	1.45@1.55
Rye, new crop	1.50@1.60
Alfalfa seed	18@20
Mustard, brown	4½
Millet	2¾
Flaxseed	5@5½
Broom corn seed, ton	23.50

Feed Stuff.

Bran, ton	29.00@30.00
Feed cornmeal, ton	34.00@35.00
Cracked corn	34.00@35.00
Ground barley, ton	23.00@24.00
Rolled oats, ton	29.00@31.00
Middlings	34.00@36.50
Oil cake, ton	40.00@41.50
Cocoanut cake, ton	24.50@25.50
Mixed feed, ton	25.00@27.00
Shorts	29.00@31.00

Almonds

Under date of January 5, J. P. Dargitz, of the California Almond Growers' Exchange, sends the following information to members:

"We have had offers for sixteen cars since Christmas day, all of these too low by one-quarter to one-half cent per pound. We rejected all of them, and already five of these cars have been placed at our prices, the buyers coming to our terms.

"This cuts our available supply to not over thirty cars, and every indication is favorable for rapid movement in the near future.

"The continued dry weather will have its effect in stimulating buying very shortly. It looks now as though the first of March would see very few almonds left on our hands.

"We desire to congratulate every member upon the present market conditions and the interest shown, same being more encouraging than at any time since we took hold of the business. Also wishing every one of you the most prosperous kind of a New Year."

Citrus Fruit Market

LOS ANGELES, Jan. 11. 1911.

The cold weather and promised colder weather of the East has had a somewhat depressing effect, and some sales at low prices are reported. Auctions contain some sales reports showing as low as $1.50. This is, however, of fruit which is of low grade or showing decay. The decay is not that which is so serious later in the season, but a development from the black spot in the navel end. This trouble is difficult to detect this year, because the lack of rain has not caused it to drop from the trees as usual, so that some goes into the boxes without the knowledge of the packer. Fancy stock of regular sizes is commanding $2.50 and as high as $2.75 in most of the markets. This would indicate approximately $1.00 to the grower. Shipments are now running from 120 to 160 cars a day.

The lemon market is, if anything, stronger, and the demand is such that every offering is picked up at once and at prices slightly in advance of those of the last few weeks. The stock going forward is all of the very best quality.

Shipments.

Shipments of oranges from November 1, 1910: 4250 cars, of lemons 758 cars, or a total of citrus fruits of 5008 cars. To same date last season: Oranges 1759 cars, lemons 686 cars, total 2445.

NEW YORK, Monday, Jan. 9.—Nineteen cars of Navels and one car of lemons were sold. The market was higher on oranges and lemons. Partly cloudy.

Heavy Fence
For Economy

WOVEN-WIRE FENCES must be heavy as they have to turn animals by sheer strength of the wire. A fence with barbs is protected from excessive pressure because the animal fears the barbs. Remove the barbs and the greatest strength of the animal is thrown upon the fence. Its wires must be larger and stronger. To have a long-life woven-wire fence the fence must be heavy.

AMERICAN FENCE

is a thoroughly galvanized square mesh fence of weight, strength and durability. Large wires are used and the whole fabric is woven together with the American hinged joint (patented)—the most substantial and flexible union possible. Both wires are positively locked and firmly held against side slip and yet are free to act like a hinge in yielding to pressure, returning quickly to place without bending or injuring the metal.

Dealers Everywhere—Stocks of American Fence are carried in every place where farm supplies are sold. The Fence is shipped to these points in carload lots, thereby securing the cheapest transportation, and the saving in freight thus made enables it to be sold at the lowest prices. Look for the American Fence dealer and get the substantial advantages he is enabled to offer. He is there to serve the purchaser in person, offer the variety of selection and save the buyer money in many ways.

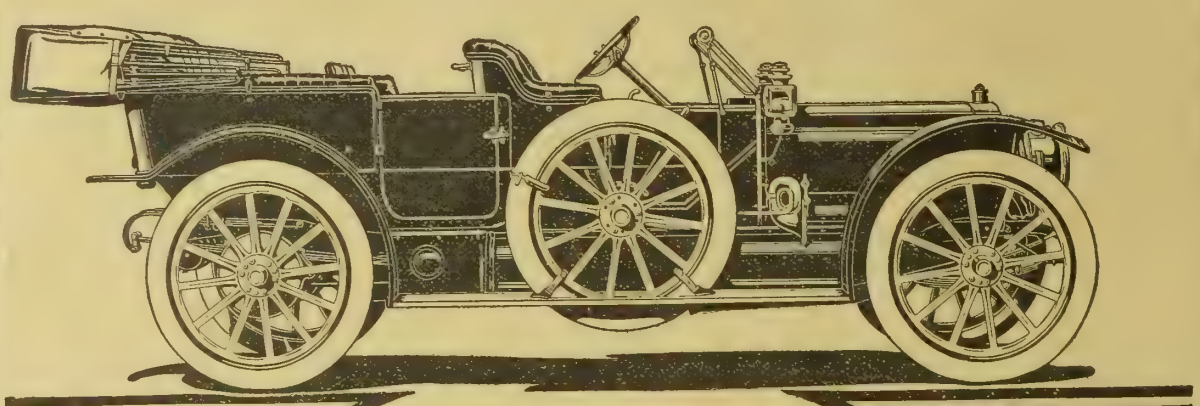
Rambler Motor Cars



Rambler Sixty-five Touring Car

COMFORT in the Rambler has been attained by careful study of owners' preferences. Forty-inch wheels, big tires, and 128-inch wheel base neutralize the inequalities of the road. Seven-eighths elliptic springs and shock absorbers soften the impact of the jolts and limit reaction. The distance between the seats and the floor is just right, and the steering pillar may be adjusted to suit the comfort of the operator. The leather and hair used for upholstering is that found in the finest club furniture. The Spare Wheel removes worry about tire trouble. The brakes, being larger than necessary, provide a feeling of security. The safety starting device protects you from injury while cranking. The offset crank-shaft and straight-line drive enable slow driving on high gear in crowded traffic, and obviate the necessity of rushing the hard pulls through sand and up grades.

The new catalogue is ready. Send for it. In principal cities, a telephone message to the Rambler representative will bring a car to your door for inspection. A postal will bring you the Rambler magazine. Ask for the name of the nearest representative.

Vol. XXXVI. No. 3. LOS ANGELES: THURSDAY, JANUARY 19, 1911 One Dollar the Year

The County Fairs as Educators in Agriculture

An Address by J. M. Eddy, Secretary of the San Joaquin county Chamber of Commerce at the State Fruit Growers Convention Dec. 8, 1910.

The State of California, through the generous suffrages of its people, has invested $5,000,000 to encourage and promote the Panama-Pacific Exposition in San Francisco, and it is the conviction of a great majority of the people of the state that such exposition will be the most successful world's fair ever held on this continent, and that the state should reap extensive and permanent benefits from this great enterprise.

But if California is to reap the greatest possible benefits from this exposition, it must be compared, to make a favorable comparison of its vast resources, its varied products, its industries and its progress, with the best that the twentieth century can show from other states and countries of the world. When the world is invited to San Francisco in 1915, it will not only expect to see a city completely rebuilt from the ashes of 1906, but it will expect to witness a reproduction by substantial exhibits of all that California boasts.

If we hope to charm the visitors and induce investment and residence in this state, then we should leave no stone unturned to have a complete and harmonious exhibit of all that the state produces—samples of all its dormant resources as well as of all its active commercial products. To accomplish this, there must be a state-wide spirit developed and a state-wide experience and habit cultivated. Much education is needed to bring the whole state into line and prepare its people and its products for the great affair of 1915.

Fairs are schools of industry and production. They denote by their comparisons what high results can be obtained by science and art when applied to the elements which nature affords. If California, in the exposition year, fails to excel all competitors in the diversity and quality of its products, then it will be a confession that either nature has not endowed this land so richly as we have boasted, or that her inhabitants are not competent to get the highest results from such marvelous resources and varied opportunities.

A world's exposition is a great university of finished products where the rest of the world is entered to outshine the local community or state which is giving the fair. The home state has every advantage of location and convenience, and consequently must make good or suffer by the comparison. But how can California make good in the university of 1915 if it has no elementary schools to feed that university?

What the common schools are to the state university, so are the county or community fairs to the state fair and the great exposition. Yet in only one county in California have there been annual county fairs for the past dozen years. Since state appropriations for district fairs were discontinued, one district after another has dropped out of the running, and today the state is entering upon the promotion of the greatest exposition in the history of the world without any local equipment or local organization of resources on which to base such a great enterprise.

In the judgment of the California County and District Fair Association, recently organized, it is as much the duty of the state to encourage, by appropriations, local fairs to feed the state fair and Panama-Pacific Exposition as it is to provide funds for the larger enterprises. On this belief is based the demand for state aid to county or district fairs.

The aid formerly extended to district fairs was during a period distinguished for cereal production. Except in a few counties, the transition from pasture and grain fields to intensified culture had scarcely begun. It is scarcely to be wondered at, therefore, with the decline in the yield and quality of grain, with the low prices prevailing during the depression, that many of the so-called fairs degenerated into racing meets, and that they were repudiated by public sentiment.

Great development has occurred in the past dozen years, and important agricultural communities have sprung up and become world-famous which were almost unknown in 1896. An inspection of the census returns from Stanislaus, Kings, Tulare, Riverside, San Bernardino and Orange counties is a significant reminder of this. New conditions have developed, and a new spirit has arisen. All over the land the farmer is demanding a new deal and a square deal. He claims that he can "come back," not as the "hayseed" of yore, but as the skilled and scientific producer of the choicest agricultural products.

The county is the unit of our political, financial, educational and social life in California. County lines are arbitrary political lines, yet, because of the government established by our state constitution, each county forms a distinct community by itself. The people mingle in the jury boxes, in the campaigns, before the tax-gatherers, and at the trading centers. The people of a county become familiar in various ways with various localities of the county, its products and its chief producers. In most, if not all, of the agricultural counties the small farmer, without much expense or great inconvenience, places samples of the best he produces in the local market place, or in a fair at the county seat, and can afford to take his family to such places of exhibit to see their own products in competition with those of his neighbors.

Such comparison arouses the spirit of progress, of betterment, and develops the habit of exhibiting the best he can produce, and producing the best that attention and industry will effect. It is distinctly educational—not only towards more perfect and uniform products for the state fair and larger exposition, but towards better commercial results, towards higher standards, choicer products for the market.

Agricultural education is in the air. It promises to become a part of the curriculum of the elementary and intermediate schools. But fairs are themselves object lessons for educational purposes, and I trust that California will not repeat the mistake it made a number of years ago when it tried to establish a great university and failed to provide for the intermediate schools to feed that university. The county fair is as essential to the success of a great exposition as the common schools are to the success of the university.

For the development of the state uniformly, and to encourage industrial effort and intensification under the most diverse conditions, the county fairs, indeed, hold first place in importance, and there is a widespread demand among the farming population that the state extend reasonable aid by appropriations to encourage the holding of such fairs. It is not presumed to be made arbitrary that every county should hold a fair, but there should be encouragement for every county possessing sufficient population and wealth to maintain a fair.

The state aid should not be so liberal as to preclude the necessity for local effort and revenue, but ample to cover the margin between success and failure—enough to minimize the element of risk until the local communities have organized the business capacity to conduct such enterprises successfully without converting them entirely into horse-race entertainments or vaudeville performances.

Ten mining counties, which contributed one and a half billion dollars in gold to the nation's wealth, are shown by the recent census to be losing population. A trip to those counties discloses no substantial improvements as an offset to the wealth they have yielded to the world. The gold taken from their mines has built palaces of marble in San Francisco, New York, London and Paris, but no good roads, no sightly public buildings, no monuments of usefulness in the mountains themselves. Their baser minerals, their timber, their water and their power are now being taken to complete the scheme of centralizing benefits and wealth in the great cities.

Impressed with the fate of mining counties, is it strange that the farmer should be warned to avert the same fate for the agricultural counties? Not only in California, but all over the United States, he is demanding a share in the largesses and patrimony of the state and nation. He refuses to be silenced by a packet of parsnip seed bearing the frank of his congressman. He wants more substantial evidence of his partnership in the affairs of our government. And while he cheerfully votes five millions for an exposition in San Francisco, and a ten-million-dollar tax on his commerce for shipping conveniences in San Francisco, and permits state funds to be used for a $250,000 exposition building in Los Angeles, and liberal endowments for state fairs in Sacramento and Oakland, he should demand, and is demanding, that the community fair, the county fair, be re-established by state aid within reach of his own vine and fig tree.

PASTURE SCENE NEAR THE MOKELUMNE RIVER, SAN JOAQUIN COUNTY

LARGEST CITRUS NURSERIES IN THE WORLD

Parties contemplating the planting of citrus groves this coming spring will do well to send for our prices soon, as there will evidently be a shortage of strictly first class stock. Write today for particulars, or, better still, pay us a visit so that we may be able to show you just what we have.

Our finely illustrated booklet, "Citrus Fruits," covering the industry from the seed to the market, mailed to any address on receipt of 25c in stamps.

Citrus and Tropical Fruits

NITRATE OF SODA AS A FERTILIZER FOR CITRUS TREES.

By E. O. Essig.

The use of nitrate of soda was somewhat discouraged at the late soil convention held in Los Angeles, it being the general contention that it would in time supply enough black alkali to practically kill the soil. Since this convention there has been much discussion that has given little satisfaction as to the validity of this belief. The following correspondence may be of interest to citrus growers:

"December 10, 1910.

"Dr. Cyril G. Hopkins,
"Agricultural Experiment Station,
"Urbana, Ill.

"Dear Sir: I take the liberty to write you only after being requested to do so by many of the citrus growers of this county, concerning the matter of the use of nitrate of soda as a fertilizer for orchards. Dr. King warned the growers against this practice, but did not make the contention perfectly plain. Since that time, others have taken up the matter and are wont to discredit this advice. At the present time many of the growers are applying all of the fertilizer that the trees will stand (from 500 to 700 pounds per acre; bearing trees). The advice sought is this:

"Will the alkali, formed by such applications, be in quantities sufficiently large to materially injure the soil? Will such injury be great enough to offset the additional cost of more expensive fertilizer (other than nitrate of soda)? How long will it take, under average conditions, to render the soil unfit for citrus culture?

"These questions are to be answered only in a general way. We simply want to know whether to use nitrate of soda or not. If we can, it is much cheaper. If we cannot safely do so, we should know it at once.

"Thanking you for any advice you may give, I am,

"Very truly yours,
"E. O. ESSIG."

"Urbana, Ill., Dec. 27, 1910.

"Mr. E. O. Essig,
"Horticultural Commissioner,
"Santa Paula, Cal.

"Dear Sir: My absence has delayed replying to your letter of December 10.

"The question whether you should continue to use sodium nitrate as a source of nitrogen for the production of citrus fruits involves so many unknown factors that I am sure I could not give you any satisfactory answer of local application with so little available information concerning other factors.

"With our detail soil survey and complete invoice of fertility on hand, taken by chemical analysis, we are rapidly acquiring sufficient information in Illinois to enable us to give very specific advice concerning the necessary treatment for profitable and permanent systems of soil improvement in this state.

"Thus, if a man will tell me in which ten acres of land he is interested, in any one of the Illinois counties where our work is completed, stating the location of his land according to the government survey, then I can tell him what type or types of soil he has, and can also give him the invoice of each type; but I do not understand your state has as yet undertaken to secure information in any such detail.

"In general, I may say that an application of 600 pounds of sodium nitrate will result in increasing the amount of sodium carbonate (black alkali) in the soil to the extent of about 400 pounds per acre, which would amount to a ton per acre in the course of five years, assuming that the sodium nitrate is applied only once each year. A ton per acre corresponds to .1 per cent in 2,000,000 pounds of soil, corresponding to about 7 inches per acre of normal soil.

"Of course, the effect of this addition of alkali upon the crop will depend upon the amount of alkali otherwise contained in the soil. If the soil is already near the danger point, it is possible that this addition might become an important factor of injury.

"It is possible, on the other hand, that some of your soils contain no alkali, but may even be acid in character; and, in such case, sodium nitrate would not only be the cheapest but probably the best form of commercial nitrogen you could use. Long continued agricultural field trials with moderate applications of sodium nitrate, at the Rothamsted Experiment Station, have shown that this material finally induces very bad physical condition, destroying the flocculent or granular character of the soil, so that it puddles easily and becomes less and less pervious to water.

"You may realize, of course, that in the absence of specific information concerning the true invoice of the soil, both with respect to total plant food present and with respect to kind and content of soluble salts, it is impossible to give specific advice concerning any particular field.

"I surely hope that your state will make more adequate provision for soil surveys and soil investigations by your experiment stations.

"Very truly yours,
"CYRIL G. HOPKINS."

THE RATIONAL AND IRRATIONAL USE OF NITRATE OF SODA.

By William S. Myers, New York.

Some time since a convention of horticulturists in Los Angeles discussed the question of the accumulation of Black Akali in the soil.

One speaker made the statement that the use of nitrate of soda would result in such accumulation—stating that in England this had become the case, and that English farmers were avoiding the use of nitrate.

The incorrectness of this latter statement is shown by the fact that the use of nitrate of soda increased last year by ten per cent in England, and its use is constantly growing there; and nitrate is coming to be more and more appreciated there as it is on the continent of Europe.

In fact, everywhere in the world where there is progressive experiment station work, the unique qualities of nitrate of soda are putting it ahead of every other nitrogenous plant food. Nobody who advocates the rational use of fertilizers ever recommends such large quantities of nitrate of soda per acre as would result in any abnormal accumulation of alkali salts. Moreover, the use of acid phosphates, associated as they are frequently with sulphate of lime, converts any alkali residue into harmless forms of soda.

Besides, of the vast majority of soils in the United States, probably ninety-five per cent have a tendency to grow acid rather than to grow alkali; and nitrate of soda is therefore highly beneficial in the majority of such cases.

The use of potash salts tends to leave acid residuals, and when phosphates and potashes are used rationally, and in quantities suitable for normal plant feeding, the question of nitrate of soda leaving an alkali residue becomes a purely fanciful and highly theoretical, rather than a practical one, and is not worth the serious attention of a practical business horticulturist or farmer. Nitrate of soda is needed to help neutralize these residues.

In all of our literature we recommend the rational and not the irrational use of fertilizers; i. e., normal amounts of the three (3) elements of fertility. We never recommend the use of nitrate of soda alone, except at the rate of one hundred or two hundred pounds per acre, which is a trifling aplication; and we always advise, when larger amounts are used, that the horticulturist or farmer use as much or more in quantity of the phosphates and potashes.

On the other hand, in the case of ninety-five per cent of our soils, the use of acid phosphate tends to leave acid residuals; as sometimes do the potash salts. The actual need of nitrate of soda is therefore apparent.

The vast majority of farm lands of our country, where so-called "Complete fertilizers" have been used, have the tendency to become sour and acid; and nitrate of soda not only could be used indefinitely with an extremely beneficial effect for this particular purpose, but there is an immediate need for it.

EXPERIMENTS IN DATE CULTURE.

The work of the Department of Agriculture in the introduction and distribution of dates bears promise of being of great commercial worth to some of the arid sections of the Southwest. The plantings near Tempe, Arizona, under the direction of the Department of Argiculture, with the cooperation of the Arizona Experiment Station, have made an excellent showing this season. The experiment station has sold this year over $1,600 worth of dates, some of the trees showing best of fruit three years from seed planting. It is a peculiarity of the date that these seedlings bear younger than do plants coming from suckers. This allows early determination of the worth of the new plants. The finest fruit has been obtained from the Deglet Noor and some of its seedlings. The effort of those in charge of the experiments has been to secure trees producing only the finest grade of fruit. The ordinary commercial date, such as sells in the market for ten and fifteen cents a pound, is not considered profitable enough to encourage its growth in California and Arizona

Prof. Silas C. Mason, Arboriculturist with the Bureau of Plant Industry of the Department of Agriculture, informs us that the trees near Mecca and Indio, in Riverside county, will make an exceptional showing. This garden has been leased by the government for ninety-nine years. It is the property of the Mecca Townsite Company, but this company is as much interested in the success of the work as any of the department officials. The company has been processing some of the fruit, and finds it shows up remarkably well.

One valuable feature of date growing is the fact that the trees will thrive in and seem to prefer lands strongly permeated with alkali. The highest grade of fruit and the thriftiest trees have grown in soils so strong with salt and alkali that practically all other cultivated plants died in the immediate vicinity. This will make valuable these hitherto undesirable lands.

SUPERPHOSPHATE.

My opinion has been asked from several quarters on the following reference to superphosphate in your issue of December 15, purporting to represent the views of Dr. C. G. Hopkins:

"When you apply phosphorus, don't use small amounts of manufactured, acidulated, high-priced commercial fertilizers, which serve as soil stimulants, and which have been used so extensively in the Eastern states in systems which led only toward ultimate land ruin; but use larger amounts of steamed bone meal in emergencies, or, better still, larger amounts of fine ground natural rock phosphate, neither of which will ever injure any soil."

This implied charge against superphosphate is so unsupported by the all but universal experience that I cannot believe Dr. Hopkins is responsible for even the implication that properly made superphosphate is harmful per se to either soil or crops. It is true that many soils of the Eastern states have been temporarily exhausted, but this was effected by constant demands made upon them without adequate restitution of the elements withdrawn. This depletion would have been averted had sufficient superphosphate and other legitimate fertilizers been meanwhile supplied. The fertility of these lands is now being restored by precisely this means, together with judicious crop rotation.

What say the public guardians of the agricultural interests of these states (who are probably as good authority on agricultural science and practice as is the author of the reference quoted)? In Rhode Island, New York, New Jersey and Ohio, "superphosphate," "acid phosphate," "dissolved bone" and "acidulated bone" function most prominently as fertilizer materials; yet not a word of warning is raised against any one of them. The land is regaining its former productiveness, and I did not see natural rock phosphate once mentioned in any of the bulletins examined.

Aside from this argument, let me state that 1,000 pounds of superphosphate, containing 16 per cent water-soluble phosphoric acid, applied to an acre, would become wholly reverted in the top eight inches of a soil containing but .00483 per cent (48⅓ ten-thousandth, or less than one two-hundredth of 1 per cent) of carbonate of lime, and "reverted phosphoric acid," combined with lime as in this case, is neutral in reaction. Moreover, the carbonates of soda, potash, ammonia and magnesia all act in a like manner on this material, to say nothing of the iron oxide and alumina in practically all soils.

My opinion is therefore unequivocally against such a wild and groundless statement.—R. R. Snowden, Chemist and Soil Engineer, Los Angeles.

STRIFE.

The law of worthy life is fundamentally the law of strife. It is only through labor and painful effort, by grim energy and resolute courage, that we move on to better things.—Theodore Roosevelt.

Deciduous Bush-Tree Fruits

POLLINATION.

Lecture before the Portland Y. M. C. A. Apple Culture Club, by Professor E. J. Krause of the Oregon Agricultu al College.

I am sure that the question of pollination of our orchard fruits will be of immense interest to you, both from the practical standpoint, and from the standpoint of the experimental work which is being carried on at Corvallis. Every orchardist, or every man who expects to become one, should know exactly what he is going to do about the matter of pollination. The reason why he should is this: Some varieties are known as the self-sterile and others as self-fertilized.

Before I come to that I desire to take up some other reasons why fruit trees do not set fruit other than through pollination. We would like to solve, if possible, the whole reason of pollination. If that were possible, we would easily remedy it. That is why so many questions arise from so many places throughout the state. "What is the matter with my trees? The fruit is all falling off." Go and investigate, and nine cases out of ten we can tell very quickly what is the matter.

One of the points, then, which I wish to make other than a matter of pollination is this: A great deal is because of freezing during the winter. There is a severe freeze, and one may think that the trees are not injured, but if we cut open the buds we will think otherwise, and then the flower buds will hardly ever stand late freezing. The posterior of the stamen of the flower is injured in that case. There will be a great many blossoms on your trees, but no fruit. Somehow it cannot set fruit. Another point that I might mention is this. Naturally some varieties will shed their fruit. It is not a matter of pollination in that case. The Spitzenberg is one such variety. I suppose many of you know that the Spitzenberg will thin itself down to one or two clusters? The Comice pear will do the same, that is, thin itself down to one pear. Many who have orchards of Comice pears do not think it necessary to go over their trees to thin them down, and frequently if two do stick they will mature all right, but frequently also the fruit will drop from the cluster. That is to say, you have eight or ten fruit sprigs on a fruit branch. Usually it will thin itself down, do what you will.

Another point in that line is the care of your orchard. If your orchard is in very poor fertility—very poor cultivation—your fruit will have a tendency to fall. Pollination will have nothing to do with it in that case. The same is true if your orchard is in intense cultivation. That is to say, if your trees are growing too fast—are forming too much wood growth. I am sure you have all noticed young trees laden down with bloom set no fruit; instead of maturing fruit, it drops all its blossoms, and you have nothing but the wood growth. As the tree grows older the wood becomes less.

Another point is when your tree is disease infected. If your tree has anthracnose, or any of the other diseases, there will be a tendency toward falling off of bloom. Naturally, a tree in an unhealthy condition will not set as much fruit as otherwise. Pollination has nothing to do in that case.

Now I will come to pollination proper. By the term self-sterile is meant when a variety is planted in large blocks by themselves they are incapable of setting fruit. By self-fertile we mean capable of setting fruit without the intervention of any other variety. Probably some of you would like to know what we mean by pollination. We mean simply the transfer of the pollen, or the male element, to the stamen, or the female element of the plant. That is true pollination. Of course, we have to go a great deal on what is fertilization. You can pollinate until your hair is gray; if your pollination does not occur, you will not have any fruit set on it.

Some of the agencies which effect pollination are these: First of all, insects. That is the primary factor in all of our orchard fruits. Then the other factor is the wind. Certain trees, such as the walnut, depend almost entirely on wind for pollination. All those trees that have a very light, dusty pollen depend on the wind. All trees which have sticky pollen depend on insects, such, as the apple, pear, peach and plum trees.

In order to be sure of pollination I would advise keeping some bees in the orchard. If your neighbor does it for you, so much the better. As probably some of you know, bees do not generally work closely at home, so they will be apt to work in your neighbor's trees as well as yours. You must depend upon insects. Pear blight is carried by insects. The sweet, honey-like liquid, which is simply alive with the bacteria of pear blight, is sought by insects, and right there they spread the disease. The disease runs down the blossom into the branch; down the branch into the trunk, and the tree is gone. It sounds quite simple, but when you lose an orchard tree it is not so funny. You have to depend on domestic bees. You cannot depend on the wild bees. An orchard that is kept in a good state of cultivation should be supplied with a hive of bees.

When we come to consider that we need a pollenizer, the point is what it shall be. Many think it is a good thing to have one variety of trees—that they get better fruit. Or the question is, should I plant a mixed variety? By no means. It is not necessary. If you have two varieties, one being pollinated by the other, that is what we are working to get to find, varieties that have a mutual affinity, as we call it. That is to say, we have Newtowns and Spitzenbergs. The Newtown will pollenize the Spitzenberg.

Before I go any further I had probably better take up some of the effects of pollination. The first one of them is this: If a variety is self-sterile, it becomes fertile, that is to say, it will set fruit with the other pollenates, and the next point is that it is stated in some cases the fruit of the cross pollinated apples is larger. Another point is this: It is stated that it affects the color of one variety. For the last two years I have seen no evidence whatever that would support that statement. It is stated on good authority that such does occur. Some of the Western authorities give that, that is, if a Spitzenberg is pollinated by the Newtown it will be of a poor color.

Apple, Pear, Apricot and Olive

Trees are in Heavy Demand. Our stock of these is the Finest in the State.

Buy your trees from the most complete and up-to-date Nursery in Southern California. **Write** for our **64-page descriptive catalog,** just out, and **let us figure on your requirements,** whether for Fruit trees, Grapes, Roses, Forest trees or Ornamentals. Careful attention given all orders large or small. Highest grade stock at lowest prices, quality considered.

ARMSTRONG NURSERIES, BOX 117, **Ontario, Cal.**

I cannot support that statement. The Spitzenberg colors just as well with the Newtowns as it does with the Arkansas Blacks. The Newtown is the same color, and the Spitzenberg is the same color.

In size there is no increase or decrease. I think there has been too little done on this in an experimental way—mostly chance observation. When you get a man who is an observer, rather than an experimenter, he will attribute it to some cause which has absolutely nothing to do with it, but if a man is an experimenter, he will try to discover the cause. Of the commercial varieties grown in Oregon, as far as I know, for the last two years, we have had no evidence to support such a statement that the color of the variety is affected or has been affected in any way—absolutely none.

Another statement is that another effect of pollination is that you get more seeds in the apple. Of course, that has nothing to do with it. It is only of interest in an experimental way. There is this to be taken into consideration. Usually the greater number of seeds the fruit contains, the larger will be the fruit. That is a point worthy of note. The statement is also made that size decreases by pollination. In the case of Bosc pears, when the Bosc was pollinated with Bartlett they were big pears; when pollinated with Comice they were of medium size, and with Winter Nelis they were of small size. On the other hand, when Comice was pollinated with Winter Nelis it gave us the largest pears, so we have got to determine for every variety what pollination will do. You cannot predict what is going to happen. You have got to experiment—not one year, but two or three, and the result that you may attain one year may be contradicted the next. You cannot say, well that is going to come out so and so. It does not work that way.

We have found out that certain of our varieties are better adapted for good pollenizers. First of all we should be sure that the varieties will blossom at the same time, because if one blossoms one week and the other comes into bloom the next, there is no chance for cross pollination. The next point is that they should both be of commercial varieties. No use planting those that are of no commercial use. The next point is that they shall be of mutual affinity; that the one shall be able to fertilize the other—for instance, the Spitzenberg and Newtown. They should be reciprocal. The next point is this—that they should come into bloom about the same day. As you know, some varieties come into bloom much earlier than others. That can be obviated. For instance, a dwarf will come into bearing in about four years and will blossom in the third year. As you all know, dwarf trees are being used for fillers, so you can use dwarf trees which come into full bloom in three years, and in that way not lose your crop, and when you have no further use for them for that purpose, take them out.

Some have recommended that you plant about 10 rows of one and then ten of the other. That is a little too far apart. I believe I would prefer to plant four of one and four of the other. You see that makes it quite convenient in harvesting. I would recommend four rows of Newtowns and then four rows of Spitzenbergs, then four rows of Newtowns and four rows of Spitzenbergs, for they will cross any two rows and that is all the distance they have to go. If you were to use ten and one, as is sometimes recommended, the one row has too much to do with the rows all on one side. If the row you are using as pollenizer is deficient in pollen, it will hardly do. That is certainly all wrong and the bees cannot do their work. They would have a great deal further to go with five rows on one side and five on the other. You would not be as likely to get as good results as if planted two rows apart as described. Then there is the matter of harvesting. You have four rows here and four rows there, so it makes it well worth while to consider. You can well afford to go down through your orchard covering four rows and both being of a commercial variety will make harvesting easier. I have in mind one of the very finest pear orchards in the state, and probably the United States, which is set that way. First it will have four rows of Bartletts, then four rows of Anjours, and so on. Then comes the Winter Nelis and the Comice in the same way. They found it very convenient in harvesting; no more trouble than if they had all been of one kind. In case you have an old orchard I would recommend that instead of going through and grafting a little dab here and there, you go over a whole row of trees at a time.

As a pollenizer the Winter Pearmain is par excellence. At the present time that variety is not used or is not grown much. I understand, however, that that variety is going to be grown much more than it is at this time. For two years it has given us the best of results by far of any we have ever used.

For the Pears.

For the Basc I will recommend Comice; for the Comice, Winter Nelis, and for the Bartlett, Anjou. Winter Nelis and the Comice work magnificently together. We have worked for several years along this line, and we are getting results down now where it is no longer a lot of hot air. We know that we can recommend and recommend definitely what shall be planted of certain varieties. We have experimented for several years and will have to experiment for several years more.

This must be borne in mind: That as a variety is self-sterile in one locality it may be absolutely self-fertile in another. Some pears that are self-sterile in the East are perfectly self-fertile out here. There is no way of accounting for that. As I said before, they are affected by food supply and the state of cultivation of your orchard. In our work we are endeavoring to find out the best pollenizers for our commercial varieties that we can recommend to those that are best suited to various districts. We may find that a variety for the Willamette Valley, for instance, is not adapted to Hood River, and that a variety which is adapted to Hood River is not adapted to the Willamette Valley. All these points have to be taken into consideration.

The matter of pollination really means dollars in a mans' pocket when he stops to consider it seriously. The work in the United States has been going on since 1894, and it is far from solved yet as to why a variety which is self-fertile here is not so in another locality. This is one of the points that we are trying to find out.

There is a bulletin published by the college (No. 104) written by Professor Lewis and Mr. Vincent, on the pollination of the apple. One of the main points of value of this bulletin is that it gives you the time of bloom of the different varieties and which can be used to pollinate. Each bulletin is printed with a plain diagram which you can fully understand.

WIPE OUT THE THRIPS.

Action is being secured in the Santa Clara Valley to reduce the menace of the thrips. We note in dispatches in daily papers the following:

"With Warren Hyde as chairman, and H. H. Wilson as secretary, the farmers of the county effected a temporary organization at Cupertino today looking to the eradication of the thrips and other insect fruit pests which have materially cut into the crops of the valley during the past few years. At a later meeting a permanent organization will be formed and permanent officers elected.

"County Entomologist Earl L. Morris offered, as the result of wide experiment in the fight against thrips, the spraying of trees with lime, while Paul Jones of the United States Department of Agriculture Experiment Station urged the prune growers to spray their trees with crude oil and tobacco, saying that his experiments had proved this method effective in ridding orchards of thrips.

"G. B. Hemphill of Los Gatos, formerly of Hood River, Ore., urged that the farmers try open sacks with torches, at which he believes the insects will singe their wings and become prisoners. Farmers from every section of the valley attended the meeting and all urged the seriousness of the fruit pest situation."

A large capacity air compressor has been received for use in the siphon under the Colorado at the Yuma Dam.

THRIPS, APHIS

and most all other insects in the orchard, garden and field are readily killed by spraying with

ACME NICOTINE LIQUID

Acme Nicotine Liquid is not a Tobacco Extract, but a strong solution of pure nicotine of uniform strength, easily diluted, and will not injure the most delicate foliage.

One gallon makes 700 gallons of strong spray material.

Pint, $1.10; half gallon, $4.25; gallon, $8.00. SOLD DIRECT TO THE CONSUMER.

Home Grounds Beautiful

COVERING WITH VINES.

Have you ever seen an ugly girl in her old clothes and the next time you met her did you scarcely know her because she was dressed up? If you have, you understand the decorative value of vines.

The commonplace house, the building of hideous line and ugly coloring is positively transformed by proper vine planting. It has been clearly demonstrated on scientific basis that vines keep the walls of a frame house in better condition than the uncovered sections; while the ivy mantled walls of foreign lands that have stood the test of centuries is the best proof what vine planting will do in the hardening line.

While there are a number of vines, both tender and perennial, that give satisfaction, the number of practical value to the average householder is not large and may be divided into one or two classes. In choosing a vine to plant consider the purpose for which it is wanted, whether for bloom and decorative effect, to cover blank wall spaces and shut out unsightly objects, or to train over trellises, stumps of trees, fences and wires.

There are vines that grow without support and others that demand it, and to make a mistake in your class is to know bitter disappointment. Much as you admire a clematis paniculata if you count on it to cover a blank wall as would an ivy or an ampelopsis that climbs by tendrils or discs, you will not get results. It will more than gratify hope if encouraged by proper support.

Roughly speaking, vines may be classified by their habit of growing as twiners, climbers by tendrils or aerial roots, and those that require support. Another division is the woody climbers or perennials, those that do not die back each year; and the annuals or herbaceous climbers.

The annual vines for temporary use and quick effect are invaluable and include such well-known vines as tendril climbers; Allegheny vine, balloon vine, cobea, gourds, nasturtiums, sweet peas, wild cucumber. Twiners: Cypress vine, flowering bean, moon flowers, morning glory, thunbergia or black-eyed Susan and Japanese hop.

Many of these, like the Allegheny vine, wild cucumber, Japanese hop, morning glories, seed themselves and coming up year after year, are practically perennial. All the other annuals should be started indoors in flats or boxes in February or March to make good growth, the vines are not set out until danger of frost is past. They can be sown in the open in May, but do not make such good growth.

Japanese hop does better for many persons if the seed is sown in the fall where it is to grow as when started in the spring it may not come up until the following year.

Among the best known and most dependable perennial or woody climbers are the tendril growers—Ampelopsis and Virginia creeper, clematis, grapes, greenbrier, trumpet, creeper, ivy, roses. Twiners—Akebia, actinidia, Dutchman's pipe, honeysuckles, wistaria, bitter sweet.

For covering blank walls without support the most common are the ampelopsis or Boston ivy, and English ivy. As the ivy is practically our only evergreen vine—though certain of the honeysuckles hold their leaves well into the winter—it is invaluable to cover big spaces, but as it is a slow grower and apt to winterkill in cold climates, is less used than Virginia creepers and Boston ivy.

Trumpet creeper, or tecoma radicans, or tecoma grandiflora also climbs by aerial roots and is fine to cover high blank walls, though more often confined to the lower floors or for covering tree trunks and unsightly places.

The trumpet vine is perhaps better known as bignonia and should be more grown than it is for decorative purposes, as its orange flowers are very showy. For blooming annual spring pruning is desirable. Wonderful hedges can be made of the trumpet vine and it looks well growing on clothes poles with the tops cut back to make it bushy.

For trellises to cover unsightly places few vines are lovelier than wild cucumber. The most effective use of it I have seen was as a snowy covering of a blank wall that faced a city back yard from the adjoining house. It clambered well to the top and was a mass of bloom in July.

A rapid growing vine for porch use is the Japanese akebia quinata, as it is hardy and does not seem to mind other vines encroaching upon it. Its flowers are less important than its foliage.

Another good vine for a latticed veranda is bitter sweet, or celastrus scandens. Its foliage is lovely, but the berries which in some places stay on most of the winter are lovelier yet.

Perhaps most rapid and most dense shade of all the hardy vines is the Japanese kudzu. It is almost unkillable when once started and will grow fifty or sixty feet in a season.—S. F. Chronicle.

THE QUINCE.

It is not supposed that the quince industry will ever grow to large proportions in the East. In fact, from the very nature of the fruit and its uses there can never be more than a very moderate demand for it. But as a part of the home fruit plantation, or as a modest part of the commercial orchard, it is certainly deserving of more attention than it has received in the past. In fact, even when they are planted, quince trees seem to be more systematically neglected than other fruits, which is certainly stating the case strongly. The quince makes a very attractive little tree, when well cared for, with a handsome blossom, and the fruit, as an article of diet, takes a high place and deserves far more general use than it receives.—Country Gentleman.

Green manuring is necessary if you build up your soil economically. Without a sufficient quantity of vegetable matter in the soil it will not produce good crops no matter how much commercial fertilizer you use. For good crops the soil must be in a good physical condition.

Plants vary; some are more productive than others. If you do not wish to grow plants that produce poor crops, eliminate them by selecting your seed from plants that produce good crops.

Garden and Field Crops

ASPARAGUS.

Asparagus is grown for the tender young shoots which grow in great numbers from the roots early in the spring, and is considered by far the choicest of all early spring vegetables. It is in great demand in all markets, selling at very fancy prices, and is one of the most profitable crops grown. The demand for it is growing faster than the supply. Asparagus growing is still in its infancy. It is being planted only in a limited way and in but few localities. It would be more extensively grown if the proper way of planting, cultivating and marketing were generally known.

Planting can be done any time in the fall, winter or spring, when the ground can be put in proper condition.

The land should be plowed thoroughly and deep and put in good condition with a harrow. Rows should be marked off with a two-horse plow four feet apart, going twice in same furrow, making it as deep as possible. There will be several inches of loose soil in the bottom of the furrow, on which to place the plants, the crowns of which should be five or six inches below the level of the ground. The plants should be set from twelve to eighteen inches apart in the row. They should be covered with about one inch of soil when planted in early fall or spring, and as soon as they commence to grow the dirt can be worked to them with cultivator until the ground is level. If planted in late fall or winter it should be covered with two furrows with a one-horse plow. The ridge thus formed should be worked down very early in the spring with disc or cutaway harrow, going as deep as possible but not deep enough to injure the plants.

One year old roots should be used. The practice of planting two, three or four year old roots should be discouraged, as it has been thoroughly demonstrated that one year old roots are superior to others in starting an asparagus field.

It should do equally as well planted in the fall as the spring. There is an advantage in fall planting from the fact that the ground can be got in better condition and the work is out of the way for spring when everyone is busy. From experience I find September planting very successful. The plants will make considerable growth in the fall, and the following spring every plant will start out strong and thrifty shoots.

I would, however, advise the planting at whatever season best suits the planter. A field when once established will last for years. I know of many fields from which asparagus has been cut for thirty years, and they are still producing good crops.

After the field has been thoroughly worked with disc or harrow in the spring, as described above, use the cultivator as often as necessary to keep the ground in good loose condition, and keep all the weeds out of the rows with a hoe. The cutting season will last about two months, during which time the field should be cultivated often.

Asparagus should be well fed with manure or commercial fertilizer which can be applied at almost any season of the year. Manure is either spread on top of the row late in the fall and covered with a plow, thus leaving a ridge until spring, or is applied in a furrow close to the row, either in spring, summer or fall. This gets the manure close to the roots and is considered the best way to use either manure or commercial fertilizer. Stock peas can also be used to help in fertilization and to keep the soil loose. They can be sowed broadcast when the cutting season is over.

Salt is a good fertilizer for asparagus, and if applied early in the spring will not only assist in fertilizing, but will greatly retard the growth of all other vegetation so that during the cutting season there will be but little growth of weeds or grass. A cheap grade of salt can be obtained for this purpose.

In the fall all the asparagus tops should be mowed and removed from the field. Then take the plow and throw two furrows on the row after applying the manure.

Cutting for market commences one year after planting and as soon as the stalks are a few inches high.

The cutting should be very light the first year, nor should the season be long. The second year, more may be cut, and the season may be longer. By the third year the asparagus field will have reached maturity, and the cutting should include every stalk that puts up, and may continue as long as the market will justify and the weather will permit. The shipping season of the well-matured field will last from six to eight weeks, sometimes longer. It is not advisable to continue cutting after the stalks commence to diminish or spindle.

Keep all the stalks cut during the shipping season, even if some are too small to ship. The cutting should be done every day during the shipping season. The stalks are tied in bunches with tape or rubber bands, each bunch containing a handful of stalks.

They should be graded according to size, making two or more grades, as may be necessary in order to have the stalks uniform in size. The stalks in the center of the bunch should be as large as those on the outside. After the stalks are bunched with a large knife cut the butts of the stalks smooth, leaving the bunch the proper length for the box.

They are packed in sectional boxes, each section holding one bunch, with twenty-four bunches to a box. When packed the box and contents weigh about fifteen pounds.

It is well to make at least two grades of your asparagus, putting nothing but the very best in your first grade. Care should be exercised to have the bunches neat and uniform.

There is always a good profit in asparagus, but strictly fancy stalks always sell for the highest price. To get the best price grow the best asparagus by liberal cultivation and fertilization, and pack it so that it will be attractive.

It is a vegetable that can be made productive of profit to a point in excess of citrus fruits, peaches or trucking.

The average annual profit per acre from asparagus that is thoroughly cultivated and fertilized and properly marketed may be placed anywhere from $200 to $300 per acre. There are instances where the net profit is still larger, and I have heard of one grower who has so thoroughly cultivated and fertilized, and with one of the best markets, that he makes more than three times this amount per acre each year.—W. W. Thomas in Florida Fruit and Produce News.

LANGDON'S TOMATOES

"I have tried all the various strains of Earliana on the market, and yours is the only one I have found that meets my idea of what a good early Tomato should be."—Prof. W. F. Massey.

J. M. Myer, Gridley, Cal., writes Nov. 28, 1910: "I tried one-half ounce of your strain of Earliana last year, and alongside of two other crack strains of Earliana yours were ripe a full week first and 25 per cent finer in every way—the finest thing in the line of early tomatoes I ever saw, and I have been at it for thirty years."

By seven years' selection we have produced the **Earliest, Hardest,** and **Smoothest** Tomato ever grown. Our location near the Canadian line tends to breed in earliness and vigor, for we have no blight. All our seed is home-grown, is extra large and plump, starting strong, vigorous plants. Send for our circular and get more inside facts.

If you want to be first on your market with perfect Tomatoes that will bring a premium over top-notch prices, plant **Langdon's Northern Adirondack Strain of Earliana Tomatoes.**

Price: ½ oz. 40c; 1 oz. 60c; 2 oz. $1.25; 4 oz. $2.00; 8 oz. $3.50; 1 lb. $6.00

TREES

Now is the Time to Plant.

Send us your Orders for Fruit and Ornamental Trees of every nature

Burbank's Latest Creations

We are authorized commercial propagators and distributors of Luther Burbank's fruit introductions. We call special attention to his newest creations.

The "Standard" Prune

This new prune, which is, without exception, the finest fruit of its kind ever introduced, is being offered by us for the first time this season. We can endorse it highly as an enormous and never-failing bearer, strong, healthy grower and best combination drying and shipping prune ever offered. The fruits average very large in size, are very sweet and perfect freestones.

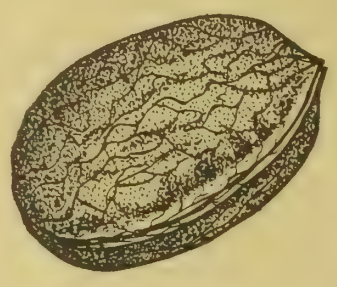
The Formosa Plum

Far exceeds all other Japanese plums in its rare qualities as a shipping fruit. A grand fruit of largest size, heart-shaped and light cherry-red in color. The trees are very magnificent upright growers and abundant producers. This variety will appeal to every shipper of high-grade fancy fruits, and we would urge you to include it in your collection. WE ARE FORTUNATE IN HAVING A FINE STOCK OF THESE TREES TO OFFER AT ATTRACTIVE PRICES.

We Invite Correspondence

From any persons desiring information about varieties to plant. Our book entitled "California Horticulture" is of great assistance to all fruit growers, not only containing detailed description but instructions for planting, care of stock, pruning, etc. The price is 25c, but to all persons who will send us a probable list of their wants for prices we will send this book **FREE**; also our NEW ILLUSTRATED PRICE CATALOGUE—something novel. Be sure to mention this ad when writing.

Walnuts



Without exception we have the finest block of these trees we ever had to offer, and we have no hesitancy in inviting you to place your orders with us.

In French and English types grafted we offer such varieties as

Chaberte Cut-Leaved,
Franquette (Vrooman Strain),
Parisienne,
Praeparturien,
Burbank's New "Santa Rosa."

Also Placentia Perfection, in both grafted and seedling trees; Seedling Santa Barbara Softshell and Ford's Improved. California and American Black Walnut Seedlings.

Walnuts are being planted more extensively than ever before, having proven highly profitable in many parts of this State. They yield splendid returns, and with proper care and cultivation, respond with such bountiful crops it will be well worth your time to consider the advisability of planting these trees.

Entomology and Bees

HOW TO FIND THE QUEEN.

There is no short cut toward finding a queen. You have got to look till you find her. Do not use much smoke, or you will set the bees to running, and then it is very hard to find a queen.

A frightened queen will run from the light and hide in the first crack or dark place she can find.

Care at the start, so as not to stampede the bees, is the great secret of success, and this, coupled with a strong light and knowledge of how any queen behaves under such conditions, gives you the key to the whole matter.

Open the hive slowly, without a jar, and use as little smoke as possible. Be very careful not to kill a single bee, for if bees are killed, the colony is liable to resent it. This causes so much smoke to be used in quieting them that the whole mass is likely to be stampeded.

If care is taken not to disturb the bees and get them to running, there is very little likelihood of the queen leaving the brood combs.

There is no use wasting time in examining frames of honey. The same might be said in a certain degree regarding combs filled solid-full of brood.

As a rule, you will find the queen on a comb or that portion of a comb from which the bees have recently emerged.

During a honey-flow, with a colony not excessively populous, gentle bees clinging to the combs, the simplest way is to take the combs out and examine them.

Put them in the comb-basket, and, if the queen has not been found, look over them again, putting them in another comb-basket. Look in the hive also.

It is necessary to use as little smoke as possible, so as to avoid starting the queen to run and hide.

Always begin at one side, first blowing a little smoke between the comb and the wall of the hive, so as to drive the queen between the combs if she happens to be against the wall.

I then take out only one comb on that side, and begin on the other side, continuing throughout. The object is to prevent the queen from being left on the walls of the hive.

One of the plans is to put the combs in pairs, having the pairs a little distance apart, using an additional hive for the needed room.

After a time the bees without the queen will show signs of uneasiness, and the operator may look for the queen in the brace of combs where the bees are quiet.

If a queen is removed from a hive very carefully, a colony may not discover its loss for some hours, while the loss may be discovered in a less number of minutes if the bees are forcibly thrown from the combs, or if otherwise roughly handled.

You will not be likely to find her on one of the combs that contain unsealed brood. If you do not find her after looking two or three times over the combs, the likelihood is that you will not find her if you keep on for half an hour.

But if you close the hive, and come back in half an hour, you may find her then the first thing.

In favorable circumstances such as are described in the beginning of this article, and if the operator has been careful and has not scared the queen, she will be found on the combs, and often she has not even interrupted her work of laying eggs.

Generally she has retreated from the light and taken refuge between the bottom of the comb and the bottom-bar, if there is space there, as there generally is.

Then, when the operator looks over the comb, there begins a game of hide-and seek. When the operator looks for the queen, he always turns the comb and himself so hat the sun will be at his back and strike on the comb.

As soon as the comb is in that position, the queen skips on the opposite side, remaining near the bottom and among the bees that are there; for the bees, as well as the queen, have retreated to the lower part of the combs, except those that are filling themselves with honey.

Then, when the operator turns the comb over, the queen skips again on the other side; not that she cares for the operator, but to get away from the sun and light.

Some beekeepers, when they desire to find black queens, take all the combs out, take the hive and dump it in front of the entrance, set it back, and clap an entrance guard over the now empty hive.

The bees are all shaken off the combs, and the entrance guard is eagerly scrutinized to see when her majesty strikes the obstruction.

We do not know but, all things considered, this is about as quick a way to find black queens among black bees as to undertake the very uncertain and laborious method I have already described.—Farm World.

SELECTION OF DRONES.

The selection of drones is one of the things in which the vast majority of bee keepers are notoriously careless. Queen breeders will select a breeding queen with great care and allow her progeny to mate with drones from any hive in the apiary, and just as long as this is done there can be no advance in the types. Drones should not be allowed to fly except from colonies where the queens are prolific and the bees good workers, and just as much care should be exercised in the choice of colonies for the production of drones as for breeding queens. The mere fact that mating takes place in the air, out of the control of the bee keeper, is no reason why care should not be taken in the selection of drones which are allowed to fly in the yard. When breeding any race, Italians for example, it is not enough that all the drones be Italians; they should be selected as to honey production of the workers, prolificness of the queen, or any other quality which is considered in choosing a breeding queen.

Selection of drones may be accomplished by the use of drone traps or by cutting out drone comb. For absolute safety the drone trap is preferable, since some drone brood may escape observation. When most colonies are requeened every season, only queens of breeding value should be kept, since old queens produce larger numbers of drones.

The building of the Riverside Creamery at Arlington was burned last week.

Live Stock and Dairy

Dairymen and stockmen are requested to write of their experience. Mrs. Sherman is always willing to answer queries and this, with experience of other workers, will make this department of greater value.

WHOSE LOSS.

(Continuation of Article in Issue of January 5)

By Mrs. Minna E. Sherman.

Now on the other side of this question stands the dairyman with his herd of untested cows. The cows may not be valuable ones and certainly, if they are not tested cows, they are not as valuable as they were a few years ago before the tested animal was in the markets. Now when the cows are tested those that react should be butchered and if on examination not more than two places are affected, one a vital spot, or if the tuberculosis is not of a generalized type, the beef is used for food. The dairyman should then be satisfied with the price he receives for her as beef. She would have grown worse on his hands and died, making a total loss for him. When the cow proves unfit for beef and is sent to the rendering and fertilizer tanks, then the dairyman should have the difference, it is contended, between the beef price and the tankage price made up to him from state funds.

Suggestions.

It is a difficult question to answer, but there is an answer somewhere that is just to everyone concerned. If the press scares the public enough with its cry of "Wolf! Wolf!" it may result in good after all to the persecuted dairyman. At present there are only a few people that will pay the price of certified milk, the average consumer would rather spend the money for hobble skirts or moving picture show tickets. I ran a dairy before the days of certified milk on lines more exacting than those called for by certification. I did not find any one willing to pay more for the milk than they gave dairies that were rankly dirty. The only satisfaction I got was in doing things right for the sake of doing them well. Then when butter making became the business, during the summer the extra cream was sold to the ice cream trade. One man started in to sell away below the then low market. I did not care particularly and said so, for the custom of the ice cream men. After a time the undercutting man found that he was losing money and sent me word he would like to sell out. I went to see his cows and saw one heifer down and two that were coughing. I told him I did not wish them and that his cows were diseased. The next week the herd was sold off at auction after the sick ones were removed, and the trouble was scattered around. At that time there was no health officer and any one would have laughed at the thought that this man did not have the right to sell those cows to any purchaser.

Bovine vs. Human.

In the human family the type of tuberculosis in most cases is not the same as that of cows. About ten per cent only of the cases in babies are of the bovine type and about two per cent in adults. While this is not as serious as we thought a few years ago, still it is serious enough. The contagiousness of the trouble is proved by the way pigs using milk from diseased cows are infected. The great increase of tuberculosis that followed the feeding of the skim milk from the creameries to calves and pigs resulted in the sterilizing of the skim milk by raising it at the creamery to a high temperature before sending it out to the farmers. The infection of the human family with the bovine type of tuberculosis is a fact, but it is surprising that it is not more frequent, when we consider how rapidly the trouble spreads among cattle.

Testing.

It is often said in derision that a small pail will hold the milk from a cow in the certified herd. Testing causes a falling off in condition for a time in the cows that do not react. This may be the result of nervousness. The tuberculin test is applied to the cow by taking her temperature three times, at regular intervals before injecting the serum. This establishes her normal temperature. Then the tuberculin is injected into the side of the neck and after eight hours the temperature is again taken three times and the effect of the tuberculin is seen by a rise of temperature called a reaction if the cow is diseased. If she is healthy no reaction or rise takes place. There are many cows that are weeded out as unprofitable by the dairyman that are really diseased. This has caused an undue amount of diseased cows to appear in the slaughter houses and from that the startling averages to show the number of cows diseased in the country are made up. A diseased cow may appear healthy but is a spasmodic milker, giving a large amount of milk one day and then falling off and running along in an irregular way in the amount of butterfat as well as in the milk. These cows are sent to the butcher naturally by the dairyman and raise the estimate of diseased animals.

City Ordinances.

The illy conducted attempts to suppress this disease among cows furnishing the milk to the city trade have been added to by another example in the city of Portland. The newspapers led in this campaign with hue and cry and the city passed the ordinance to test the cows. Considerable loss was borne by the dairymen at first, until one refused and appealed to the circuit court, when Judge Clelland made the ruling that the city could not go out into the country and test cows. All the city could do was to examine the milk offered for sale and reject it if it was detrimental to health, public morals and welfare. The courts will always be very slow in upholding any ordinance that acts in confiscating private property. Property in the eye of the law is sacred and the owners must not be restrained in any way in its legitimate use. The trouble was not even helped by the destruction of these cows, for the dairyman had to buy others to replace those lost. Where could he find tuberculin tested cows? Until the use is general it is almost useless for one man to clean up his herd and later have to buy untested animals.

In Berkeley the dairymen combined and beat the ordinance that tried to

Cream Separators, all sizes and prices. O. J. Weber Co., 225-227-229-231 East Sixth street, Los Angeles.

SOME OF THE REASONS WHY
the
United States Separator
Is the BEST in the World.

The United States Separator employs a feeding device to deliver the whole milk beyond the cream zone—preventing any remixing of cream and skimmilk and any conflict of currents. **No other device of any other Separator will do this work so well, as the records show.** This device is patented, and can be used on no other Separator.

The United States uses non-aligned channels for the currents of milk through the separator bowl. This is covered by strong patents. **No disks or other construction can equal its perfection in separation.** It won the world's record for skimming, in 50 consecutive runs continuing 30 days, with the milk of ten different breeds of cows.

$99\frac{99}{100}$ of the creameries use cream gathered from United States Separators—**and are eager for more.** Cream from the United States is smooth and perfect for butter making.

The United States skims cleaner, runs easier, washes easier and lasts longer than any other separator. Ask the man who runs one. Ask us for catalogue No. 20 at once.

compel testing the cows. The people of this town are generally considered above the average towns in education and in public spirit, and yet the protection desired could not be secured. The testing and rejecting of a number of cows some years ago around San Jose resulted in their disappearance, and when the authorities went again to see them they had gone. They were sold away and no one had authority to follow them into new districts. The disease was spread into new counties in this way. We often say we are a new country and back East they do things in better ways. I wish it was true, but take the instance of one of the New England states that tried to pay a small bounty on the cows destroyed. The packers from other states found it a convenient market to sell off cows.

National Aid.

If there cannot be found shortly a serum or vaccine to protect the cows from infection, destruction of the diseased ones must come and the question of paying for cows must be met. The serum protection has been secured in a limited degree and may be applied to young animals that are dropped by diseased cows. The Bang system will save the offspring from valuable cows and those who have fine-bred herds will use it. The trouble today is not with the breeder of fine cattle controlling the trouble. He has too much money invested not to safeguard his herd in every way. The trouble lies in the market milkman who buys cows, uses them for a time and then turns them off as beef. The enlightened public opinion must come to force forward the formation of a national department of public health. Then the law and amounts paid could be made uniform. Cows that reacted could at least be branded by the United States as condemned and then the local authorities could see that none were used in milk herds. I should like to see five years given the dairymen to clear their herds and then after that time have the cows that reacted destroyed by government authority without redress. If the matter could be pushed along promptly the herds could have the trouble stamped out in less time. It only needs time enough to secure every calf reaching maturity that has been raised on milk of untested cows. The testing taking place after two years of age may be relied on to show tuberculosis.—M. E. Sherman.

MILCH GOAT ASSOCIATION.

By Miss H. A. Wood, Pasadena.

Perhaps the following extracts from a letter received from a friend of mine in Chicago may interest some of the Cultivator readers.

"On your suggestion I attended the annual meeting of the American Milk Record association and had the pleasure of meeting Mr. W. A. Shafer, the president of the association, and J. C. Darst, the secretary. Mr. Darst is from Dayton, Ohio, and the largest owner of milk goats in the United States.

There were very few in attendance, but I listened to the minutes of the last meeting and what had been accomplished during the past year, with interest. This was the sixth annual meeting and the keeping of this organization in existence seems to have been quite an effort for the reason that there are very few people who make a specialty of keeping milk goats and there are practically no importations of this animal because of the quarantine laws which interfere to a great extent. Furthermore, there seems to be no one who is willing to put up the amount of money to import these goats. The government however, is interested in the proposition and Mr. Shaw and Mr. Bell attended the meeting, representing the department of agriculture. Mr. Shaw made some very interesting remarks.

There are eighty-six members of this association at the present time. The best part of the meeting consisted of an address made by Dr. Hornsby who is superintendent of the Michael Reese hospital here in Chicago. From his talk it seems beyond question that the goat milk is very superior to cow's milk. As a matter of fact he was so strong in his belief that he purchased twenty-five scrub milk goats for use at the hospital and with very good results. It was, however, very difficult for them to keep these goats at the hospital and they had to send them out some twenty miles in the country. It seems important that the milk should be perfectly fresh and if possible shipments at any long distance avoided. He was thoroughly in earnest about the importation of goats, especially for use in connection with hospitals.

The meeting although as above stated not very well attended, was certainly very interesting and I believe that the goat industry has a great future. There was one gentleman at the meeting who has a few goats on the outskirts of the city and he made the statement that he could get fifty cents a quart for all the goat milk he could furnish here in Chicago but the difficulty seems to be in the scarcity of goats."

Do your cows milk hard? Send 50 cents for teat expander. O. J. Weber Co., 225-227-229-231 East Sixth St., Los Angeles.

THE SHAPE OF HORSES' HOCKS.

Strongly made, well-shaped hock joints admittedly constitute the most important point to be sought for in the conformation of the hind legs of horses of every class, both heavy and light. Indeed, of such importance is this, experienced horsemen see that the hocks are among the first points to which he directs his scrutiny. The reasons to be adduced why so much stress should be laid upon this requirement are as follows: Firstly, because the degree of propelling power developed by the hindquarters depends more than anything on the strength possessed by the hocks. Secondly, because these points are the principal seat of unsoundness and lameness in the hind leg, just as the feet and back tendons are in the case of the fore limb; hence it is most desirable that they should be as strong as possible. And a third reason is because good hocks are essential to satisfactory action behind.

The fact of the hock being strong is mainly indicated by its contours, as well as by its possessing a comparatively long as calcis, which is the bone at the back of the joint, and the upper end of which forms the so-called point of the hock. In judging of the shape of the hock joints, three or four features should primarily be looked for as being the principal desiderata. A large size especially is all-important, for small hocks are never strong; so that horsemen generally regard the expressions, "small hocks" and "weak hocks" as practically synonymous. They are far more liable to suffer from the effects of wear, to become unsound, or to throw out a curb than

large-sized ones. A further important requirement in hocks of good shape is that they should be bent at a proper angle in front. It is an objectionable feature if the hock joint is unduly straight, as this involves a grave mechanical disability, in that it prevents the horse from using its hocks to the best advantage, because it cannot straighten them out to the extent as where these joints are more bent in shape. Consequently there is a loss of propelling power; while secondly, hocks of this kind are subjected to more wear than is ordinarily the case, inasmuch as they suffer a great amount of concussion. So-called sickle hocks comprise a fault which is the exact opposite to straight hocks, the joints in this case being bent to an undue extent. This defect is rather unsightly, especially if at all pronounced, and it is certainly a good deal more so than the former, which quite usually entirely escapes the notice of an inexperienced observer. For this reason sickle-shaped hocks are very commonly regarded as constituting a more objectionable failing than straight hocks, but in reality the reverse is the case. A sickle shape of the hock joints, too, means a reduction in the propelling power of the hind legs, yet not nearly so great a one as is entailed when these parts are too straight, while sickle hocks wear much better. Horsemen often speak of coarse hocks. This expression is practically self-explanatory, meaning that the hocks show a want of refinement in their outline, or are not as symmetrical in shape as they might be, there being unduly noticeable prominences. Although they are generally considered an undesirable feature, there is not much to object to in coarse hocks, for hock joints of this kind are usually of large size and that is a valuable attribute. The term "curby hocks," which is frequently used, has a rather indefinite meaning, though it is mostly applied to hocks in which the rear outline is not quite straight (viewing the joint in profile) but somewhat curved outwards, giving the idea of the curb. It is often said that curby hocks are more than ordinarily liable to spring a curb, and they are objected to for that reason, but as often as one finds such hock joints to be quite as strong and no more predisposed to contract unsoundness, than more normally shaped ones. Still, the fact of a horse being curby-hocked must be looked upon as a disadvantage. Sometimes the opposite kind of formation is seen, the hock looked at sideways, showing a more or less concave outline behind. That is practically always an indication that the joint is weak, and this feature is to be strongly objected to.—N. W., Pacific Farmer.

IS TUBERCULIN RELIABLE?

Certain skeptics seem to think that it is very conclusive to constantly assert that the tuberculin test is not reliable. How reliable it is, when intelligently administered, may be gained from reading the address of Dr. H. E. Talbot, of Des Moines, Iowa, before the Iowa Veterinary Association. He reports 1,000 cases of cattle tested, of which 306 reacted, thus showing the presence of the disease. Of these 306 reacting cattle, all were slaughtered at packing establishments and turned over to federal inspectors. According to the report of the United States inspectors, of the 306 slaughtered, 305 showed marked tubercular lesions, proving the test to be 99.9 per cent reliable. It may be fairly pertinent to ask of the skeptics as to how reliable they think the test should be. Of the 306 slaughtered, 76 were consigned to the tank as unfit for food, being 7.6 per cent of the entire number tested, or 24.8 per cent of the reactors.

The Wisconsin station has made interesting tests to prove relative sizes and weights in litters from young and old sows, with astonishing results. In these tests sows weighing an average of 482 pounds at farrowing time produced an average of 9.2 pigs per litter, with a weight per litter of 27 pounds. From sows weighing 307 pounds the average number in the litter was 6.7 pigs, and the weight of the litter was 16 pounds. Where the average weight per sow was 238 pounds the average number in a litter was 5.5 pigs and the average weight of a litter 14 pounds. Sows between the ages of four and five years averaged nine pigs to a litter and a weight per litter of 26 pounds; sows between two and three years old had an average litter of 7.5 pigs, and a litter averaged 19.7 pounds in weight, and sows a year old produced litters of 7.8 pigs, with an average weight of 14.2 pounds per litter.—From Coburn's "Swine in America."

A Wonderful New Gasoline Farm Wagon and General Farm Power Machine

Here is the machine that Farmers everywhere have been looking for—a machine that will really take the place of horses for general farm work

Road Work FieldWork Belt Work

Will Do More Kinds of Work Than Any Other Farm Power Machine

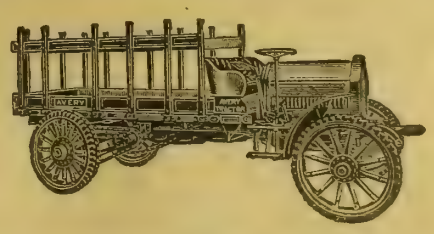
This is the first and only machine that is a Combination Farm Wagon and General Farm Power Machine. It *carries* loads on its own body, *pulls* plows and other machinery in the field and *drives* other machines by belt power. You can do *road work*, *field work* or *belt work*, *all* with this *one machine*.

Entirely Original in Design

All other farm power machines are designed only for furnishing pulling power, but not for carrying a load. The Avery Tractor is the first and only machine built that furnishes power for field or belt work and will also carry loads on its own body.

It is the first and only machine with a variation of speeds of from three miles per hour for slower, heavy work, or up to fifteen miles per hour for fast traveling with a light load.

It is the first and only machine that has a wheel construction that gives it a good footing on a hard dirt road, a macadam road, a muddy road or in a soft field.



THE AVERY FARM TRACTOR
The Wonderful New Gasoline Farm Wagon and General Farm Power Machine

The Story of Its Invention

Everywhere men have been looking for a machine that would really take the place of horses for general farm work.

Many machines have been built to meet this demand, but none of them have been of a design that made them suitable for general use on the average sized farm.

The Avery Company has recognized this need and has been working on the problem for a number of years, and at last, after long and careful planning, experimenting and testing out is now able to offer the *first successful machine* to do the *work of horses* on the *average sized farm*.

Many have already been sold and are in successful use. Severe tests have proven that they are able to stand up under hard service and that they are reliable.

Find Out at Once About This Wonderful New Farm Power Machine

Our free catalog gives full description of its construction as well as pictures showing it doing a large number of different kinds of work. Ask for a catalog, and find out all about the *Avery Gasoline Tractor*.

CONTENTS THIS WEEK

BIRD'S-EYE VIEW OF ORCHARDS OF WENATCHEE VALLEY, Cover.

COUNTY FAIRS AS EDUCATORS, 67.

CITRUS AND TROPICAL.—Nitrate of Soda as a Fertilizer; Rational and Irrational Use of Nitrate of Soda; Date Culture; Super-Phosphate: 68,69.

DECIDUOUS BUSH-TREE FRUITS.—Pollination; Wipe Out the Thrips: 70, 71.

HOME GROUNDS BEAUTIFUL.—Covering With Vines; The Quince: 72.

GARDEN AND FIELD CROPS.—Asparagus: 73.

ENTOMOLOGY AND BEES.—How to Find the Queen; Selection of Drones: 74.

LIVE STOCK AND DAIRY.—Whose Loss; Milch Goat Association; Shape of Horse's Hocks; Is Tuberculin Reliable: 75-77.

EDITORIAL.—The Nubbin in the Fair Bin; Orchard Planting in Washington; Oranges by Panama; State Bee-Keepers' Meeting; Citrus Breeders' Association; Notes on Frost: 78.

AGRICULTURAL NEWS NOTES OF THE PACIFIC COAST.—Northern, Central, Southern, The Coast: 79.

PRACTICAL POULTRY CULTURE.—Feeds for Poultry; About Incubators; Successful Matings: 80-83.

IRRIGATION AND FORESTRY.—Creosoting of Fence Posts: 84, 85.

QUESTIONS AND ANSWERS.—Ground Squirrel Eradication; Eucalyptus for Malaria; Poison for Ground Squirrels; Hens vs. Ducks; Rheumatism; Barrenness; Temperature for Guavas; Alfalfa for Poultry; Olive Cuttings: 86, 87.

VETERINARY.—Swelling; Brittle Hoof; Scirrhus Cord: 87.

TIMELY RANCH SUGGESTIONS.—Broom Corn; Buying Alfalfa Seed; Fly Catchers: 88, 89.

GENERAL HOUSEHOLD NOTES.—Beautiful Blue Danube; Reforming a Man; Oh Say and Oh Said; Rabbit Recipes; Homely Hints; Contentment: 91, 92, 93.

PRODUCE MARKET.—Los Angeles Market, San Francisco Market; Deciduous Market; Citrus Market: 94, 95.

THE NUBBIN IN THE FAIR BIN.

The Pacific Outlook for the current week contains a timely editorial on the present agitation for the revival of the old-time District Fairs from which we quote the following significant paragraphs:

"A determined effort is to be made to induce the present legislature to revive the district fair system. It may not prove an easy thing to do, were legislature and administration ever so willing, for the reason that only omniscience can surely foreknow what the new system of taxation, provided for in the adoption of constitutional amendment number one, is going to produce, and until that fact is known from experience appropriation will have to proceed cautiously.

"But, no matter what the conditions of the state treasury, nothing should be done with relation to reviving the district fair system without first giving the whole subject of fairs careful consideration. * * *

"What with government and state experiment stations, farmers' bulletins, pathological laboratories for the study of diseases of plants and animals; what with agricultural colleges, farming schools and short courses, demonstration trains and a great government devoting something like $20,000,000 a year to agricultural and kindred interests; what with agricultural journals and farmers' institutes with scientific lecturers laying before those who care to listen the ripest knowledge of the age, with all these the educational value of fairs is not what it once was, at least not relatively speaking, although, absolutely, there may still be great gain from fairs if only people will attend them."

The last sentence gives the nub of the whole situation. If the people will give these fixtures a united support; if the fruit growers, the producers of garden and field crops, the raisers of live stock and poultry, will make exhibits worth while, the fairs would be self-sustaining and in no way prove a burden to the taxpayers. Their value, after all, is more along lines of development and social, rather than educational, although as object lessons in an advanced horticultural and agricultural practice, they also possess a value in the dissemination of intelligence. At best, so it seems to us, the state's money, if granted at all, should be safely guarded, to the end that it would in fact as well as in theory foster, promote, protect and develop our rural economy along economic lines. To expend it in any other way would be short of nothing less than a crime.

As between county and district fairs it seems to us that the latter has much the best of the argument. To again quote from our esteemed contemporary:

"If California were to hold one great fair at Oakland or San Francisco and another at Los Angeles the admission fees, etc., would make them self-sustaining after the plants had been set up, a third at Sacramento and a fourth at Fresno would reach about all the people in the state who would care to go to fairs, the cost would be less and such fairs would do more good than to have as many district fairs as counties. Such a system helps them up and holds them down."

This again suggests the pertinent question, "Why is the average California fair a business failure? And if incapable of becoming self-sustaining, why add to the taxpayers' burdens by giving it a subsidy?" Obviously the whole matter simmers down to a question of equities. If one section of the state is to enjoy a fair, why not others? Shall we abolish the whole system, or shall it be a matter of substantial appropriations for district fairs worth while, or a number of small appropriations spread thinly over local or county fairs? That is the nubbin in the bin of Fair corn.

ORCHARD PLANTING IN WASHINGTON.

Our frontispiece illustration this week affords a splendid object lesson in the remarkable development of the deciduous fruit industry in Washington and Oregon—a growth almost without precedent in economic horticulture. The plantings embrace all the standard deciduous fruits of the temperate zone, and are especially strong in apples, pears, the stone fruits, grapes and bush berries. In Eastern Washington and Oregon the cultivated areas in fruit culture are made possible only by splendid systems of irrigation, which makes horticultural practice much the same as in California, only that our practice has become settled, while theirs is still largely in the formative stage. With California experiences to build on, the growers of that region will make more rapid progress than did early California horticulture, due not only to this fact, but also to improvements in harvesting, packing, shipping and marketing. The growth of the fruit business in Washington is somewhat indicated in the fact that of apple trees alone there are single nurseries growing stocks of a million trees at a time. Obviously, when these orchards all come into bearing, economic problems to be solved will naturally present themselves; but let us hope that when that time arrives the matter of getting the fruit into the hands of consumers at a price mutually satisfactory will have been worked out. The thanks of the Cultivator are due to the Western Farmer for the use of the illustration herein referred to.

ORANGES BY PANAMA.

The arrival at New York of the first shipment of California oranges has been awaited with interest and the result is now being studied. The offering of this first shipment which consisted of one car oranges and one car lemons, arrived last week and shows seven per cent decay of oranges and five per cent of lemons. This is to be regretted and is in part due to poor ventilation in the hold of the vessel on the Atlantic side and in part to a three-day delay on the Panama Railway owing to pressure of traffic in canal operations.

The shipment from San Pedro to Panama was on deck with only slight protection, but because of Eastern weather from Florida up, the shipment from Colon had to be in the hold. Both oranges and lemons brought good prices in New York, but not as good as if they had not shown decay.

Manager Woodford of the Fruit Growers' Exchange said: "The shipment went through in better shape than I expected. While it is not satisfactory when decay is shown, yet in consideration of all the conditions in this case, the decay is not exceptional. I doubt if under present conditions it will be possible to send great tonnage by Panama, but when the canal is opened it will be easy to ship fruit by water and have it reach New York as soon as it now goes there by rail. It is probable that 25 per cent of the present orange consumption will be in reach of water transportation, and this will lower prices to consumers."

STATE BEE-KEEPERS MEETING.

The California State Bee-Keepers Association will meet in annual session in the Chamber of Commerce Building, in Los Angeles, on Monday, Tuesday and Wednesday, February 27-March 1. The meeting will open on Monday evening with a preliminary business session, at which minutes, appointing of committees and other routine matters will be taken up. Tuesday morning will begin the interesting program. Secretary Shaffner informs us that an effort has been made to have a large number of short, crisp addresses, rather than any long or labored papers. The three days' session will call forth in the neighborhood of twenty-five of these short papers. Legislative matters pertaining to apiculture may bring forth interesting discussion. The attendance promises to be larger than ever.

CITRUS BREEDERS ASSOCIATION.

Prof. Norton of Riverside has asked the question as to whether it is not wise for California to organize a citrus breeders association. The fascination of plant and animal breeding has appealed to many, and it will appeal to more. The development of the highest type of a species is not only fascinating, but a sure profit to the country at large, if not always to the individual breeder. It costs much effort, time and money to bring out the highest perfection in plant and animal, and the reward is due to the one who accomplishes the results, but too often only fame is the recompense. If the citrus breeders of California could get together, they might succeed in so raising the standard demanded in citrus trees that nurserymen would exercise the greatest care in bud selection. Possibly it might even lead to the production of something even better than the famed Washington Navel.

Mr. Alex. McAdie, Professor of Meteorology, of the Weather Bureau of the Department of Agriculture, and in charge of the station at San Francisco, favors us with Farmers' Bulletin 104, "Notes on Frost." This is a scientific discussion of how frost is formed, seasons of frost, when to expect frost, influence of soil and vegetation on temperature, and dates of early and late frosts. Along more practical lines is an extended discussion of protection from frost. Another pamphlet, a reprint from "Climatology of California" of the Weather Bureau, discusses the situation in California and gives illustrations of various frost protection devices, one being the lath screen at the old Everest place, near Arlington Heights. That was a screen constructed over the entire orchard at great expense, but finally removed as impracticable.

The Council of North American Grain Exchanges holds a meeting in Chicago on February 8th, the entire day to be given up to the discussion of "How to obtain a larger yield of better grain." This is the first time an attempt has been made to unite commercial with agricultural and scientific interests. There will be many prominent men upon the program.

A poultryman at Oregon City, Oregon, claims a net profit of $605.50 from 173 hens.

Agricultural News Notes of the Pacific Coast

Northern California

A bill has been presented in the state legislature calling for regulation of timber cuttings in forest lands.

One hatchery at Santa Rosa recently had an increase in its chicken family to the extent of 6000 in one day.

Santa Rosa members of the Grange are planning for a two-day session of Pomona Grange.

The state legislature is to be asked to appropriate $100,000 to advertise the agricultural possibilities of this state over the East.

The normal rainfall at San Francisco from September 1st to January 1st is 8.29 inches, but this year the precipitation was only 2.91.

The Alameda County Poultry Association has elected Wm. E. Gibson, president, and W. T. Frost, temporary secretary.

The second trip of the demonstration train for this year visited sections of Sacramento, Placer and Eldorado county last week.

The Sutter Drainage District south of Yuba City is making improvements which will call for another assessment during this season.

The board of supervisors of Butte county is having contention with the Butte County Canal Co., because of bad condition of roads through canal work along and across the highways.

The Sacramento Valley Development Association is raising a $10,000 fund to encourage a further experimentation in the culture of rice in the Sacramento Valley.

Several carloads of Oregon nursery stock have been received in Sonoma county, some of which are reported to have been destroyed by the horticultural commissionr because of pests.

State Horticultural Commissioner Jeffrey reports that out of 13,072 cars of green deciduous fruit shipped during 1910, 4910 were inspected and came up to standardization rule.

The horticultural commissioner of Sonoma county reports much pruning and spraying of apple orchards has already been done. More general good care will be given this year than formerly.

Independent rand owners in Glenn and Colusa counties are conferring with the Sacramento Valley Irrigation company hoping to induce the company to resume work on its extensive system in those counties.

From all reports it is evident that wild turkeys will become very common in the national parks and forest reserves of this state. Several bands have been given their liberty within the last few months.

The Sonoma County Farmers Insurance company reports new business for the past year to the extent of $750,494 or a net increase over the preceding year of $283,545. The total insurance in force January 1st was $2,351,520.

The figures of the Merchants Exchange of San Francisco show that since 1905 there has been a material decline in the receipts of butter in that city. The '05 receipts which were the largest ever were 17,419,943 pounds. This decreased until last year there were 13,931,900 pounds.

Central California

Many dogs at Bakersfield and at Hanford have been killed because of hydrophobia which has been prevalent.

The Farmers Union reports that for the year 1911 it will make an effort to teach the farmer a way out of debt.

At a mass meeting of citizens of Tipton Irrigation District, in Tulare county, it was decided to pay off the bonds.

Fresno shippers are making an effort to have the freight rate case reopened to secure readjustment of rates in favor of Fresno.

Raisin packers opened the new year with an offer of 3½ cents for 1911 raisins. They also agreed to contract for three years for three cents.

The federal insecticide act of 1910 went into effect January 1st, and various insecticides may be purchased with reasonable surety of their being pure.

County Horticultural Commissioner Volck of Santa Cruz county, recommends a campaign of instruction of growers and spraying crews in the most satisfactory methods of applying spray.

The big sugar factory at Spreckels has a capacity of 3,000 tons of beets daily, and the valley has 90,000 acres suitable for sugar beet production. Next season's planting will aggregate 25,000 acres.

The Earl Fruit Co. is refitting the large packing house formerly owned by the C. C. U. at Porterville, and the company will make that its central office for its fruit houses in that section of the state.

Several cheers and several tigers were given in honor of the Watsonville Apple Annual at the annual banquet of members last week. The slogan for the coming year is "A greater and grander apple annual in 1911."

Articles were filed last week for the California Raisin Exchange. It is incorporated under the co-operative law. The directors are: W. R. and Myrta L. Nutting of Fresno, M. P. Hopkins, G. C. DeGarmo and E. P. Houghton of Los Angeles.

The demonstration train which toured the northern end of the valley last week and will later make a tour farther south, has an extended exhibit of models of irrigation implements, measuring weirs and photographs illustrating more modern irrigation practice.

To secure more general recognition of the citrus interests of Tulare county by the county board of supervisors citrus growers took them on a trip through the citrus growing sections of Porterville, Lindsay, Strathmore, Exeter and Lemoncove. The immediate object is to secure more liberal appropriation for the horticultural commission.

The horticultural commissioner of Tulare county has been exceptionally active in the suppression of pests and inspection of nursery stock, and the board of supervisors of the county is concerned lest adjoining counties are lax. It was recommended at a recent meeting of the board that the state horticultural commission be appealed to to insist upon enforcement of law in those counties.

Southern California

Decay is showing much earlier in orange shipments than usual.

Present prices of cotton in Imperial Valley are $13.70 to $13.80 cents per pound.

Banning, San Bernardino county, reports a fall of 5½ inches of rain during the last storm.

With potatoes near the $3 mark, those who are holding are jubilant, and extensive planting is planned this spring.

Most orange packing houses are running full handed, and total shipments are now approaching the 200 cars per day mark.

Last week's rain covered all parts of Southern California with from three-quarters of an inch to an inch and a quarter precipitation.

Pizmo Beach, San Luis Obispo county, is making its first shipments of minced clams, the cannery having supplied heretofore only local demand.

Imperial boosters are working for an appropriation of $20,000 for equipment and maintenance of an agricultural experiment station in that county.

The decision of the surveyor general in the case of rich lands near Palo Verde, in Eastern Riverside and Imperial counties, has restored about 60,000 arces to original settlers.

An effort is being made to put the Orange County Poultry, Pigeon and Pet Stock Association in a stronger working position, and to give a poultry show the coming year which will eclipse all past efforts.

The National Orange Company of Riverside has just installed nine patent citrus fruit wagons, provided with special springs built low for orchard work, and with a capacity of forty packed boxes each.

The estimate of the California Fruit Growers Exchange is that the output of citrus fruits from the state will aggregate 48,000 cars. This is 3,000 cars in excess of that made by the Riverside Press a few weeks earlier.

The grand jury of San Bernardino county recently reported: "The horticultural commissioner has accumulated one of the finest and most complete horticultural libraries in the state, also a rare collection of specimens."

The reforestation committee of Riverside, San Bernardino and Orange counties is appealing for aid from the state engineer in the measurement of run-off from the local watersheds in which rise the waters irrigating these counties.

The defunct Alessandro Irrigation District, organized under the Wright Irrigation Act, has been sued for nearly a quarter of a million dollars for bonds purchased in Europe 17 years ago. The original bonds were for $123,400, which is asked together with interest.

Mr. J. W. Gregg, whose ranch is located between Banning and Idlewild, San Bernardino county, is about to plant 1500 apple trees. Mr. Thomas Pierce, in the same section, another 1500. Mr. Hughes, also in the vicinity of Banning, is about to plant 300 acres. This section will soon be known as a large apple producer.

The Coast

Klamath Falls, Oregon, plans for the construction of a beet sugar factory.

Spuds are now selling at Seattle freely at $1.25 to $1.50.

Spokane's first heavy snowfall came at Christmas time and was greatly needed.

A great flood early in December did damage to the extent of 400,000 pesos in the vicinity of Zamboanga, Mindanao, P. I.

The recent poultry show at Spokane claims to have beaten all coast records in a single comb Black Leghorn pullet scoring ninety-seven points.

Wool growers near Salem, Oregon, are circulating a petition asking for repeal of the law which would fine farmers for allowing stock to run at large.

It is reported that sugar cane in the Philippine Islands is allowed to remain in the ground only nine to fourteen months, while in Hawaii from eighteen to twenty-four months.

Irrigators in Oregon are incensed at what they charge is negligence on the part of their senators in not securing a fair share of the $45,000,000 irrigation fund distributed in December.

Estimates of hops now on hand made at Portland, Oregon, are in effect that the supply of unsold hops has not been so small in twenty years as at present.

The Poultry and Pet Stock Association of Whitman county, is exhibiting at Colfax, Washington, a fine line of cups to be given at the show which will begin next Monday.

According to the view of the wool-growing industry presented before the National Wool Growers' Association at Portland, this has been the hardest year in the history of the wool industry.

Northwestern apple growers are figuring that with a shortage of 400,000 barrels of apples reported from the entire country, the few which are held by western growers should bring a stiff price.

As a result of the annual meeting of the Western Live Stock Association held at Grangeville, Idaho, the possibilities of alfalfa were given general discussion during almost the entire session.

The Oregon supreme court has handed down a decision which involves the obligation of railroads to furnish cars to shippers and has sustained judgment in case where damages were allowed for delay.

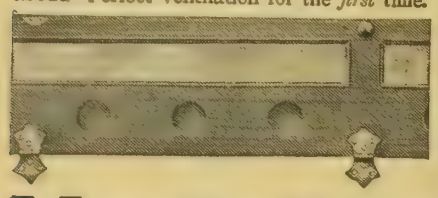
The Seventeenth Annual Convention of the Washington State Bee Keepers Association was held in North Yakima last week, and discussed foul brood and other pests of the industry.

Stockholders of the Farmers Exchange at Phoenix, Arizona, which has given its energies to marketing products of the members, have ruled that hereafter co-operative purchasing shall also be a feature of its work.

Delegates from fruit growers associations of Oregon, Idaho, Washington, Colorado and Utah have been invited to attend a meeting at Portland, January 24, to form a national apple selling agency.

More Inventions by Lee

Here's his new Incubator door all are talking about. Perfect ventilation for the *first* time.

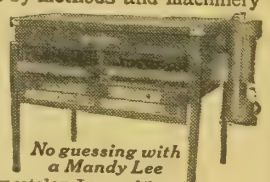


Mandy Lee Incubators

supply life-giving oxygen freely to the eggs and just as naturally draw off the poisonous gases. The most important step ever taken in incubator ventilation—neither above nor below, but *right at the eggs*—the correct principle, for the new Mandy Lee is making better hatches of *stronger* chicks than any other incubator in the world.

We Measure Everything

Heat—moisture—ventilation. You *guess* at nothing. If the eggs are good and you follow simple directions your work with a Mandy Lee is as nearly an absolute certainty as anything can be. There is no more reason why you should buy an incubator that regulates nothing but heat than for a farmer to continue to harvest his crops by methods and machinery used 100 years ago. Your success with poultry depends on your ability to select equipment that is *right*—that's what you *always* get from us.



No guessing with a Mandy Lee

Send *to-day* for new catalog. Learn of these new improvements and of our new *out-door*, *lamp-heated* and *regulated brooder*, just what is needed.

Practical Poultry Culture

FEEDS FOR POULTRY.

By Prof. M. E. Jaffa, Before Haywards Poultry Association.

Green food is a necessity in order to obtain the best results. The best green food is alfalfa where it can be grown, even under difficulties, and it will more than repay the efforts necessary. Alfalfa is the richest green food you can give poultry, rich in protein, and the more of it you have, the less concentrated food will be required, 5 per cent protein being contained in lean alfalfa, the amount in leaves being considerably more. Any other green food, except peas, contains less. Succulency is what makes the green food necessary, and green alfalfa is the very best. Kale, cabbage and the various other green foods are good.

Any dry hay is not as good as green. You must have the succulent food. Alfalfa meal will not take the place of green food.

Sprouting grain is another method of obtaining green food, and more can be grown on small space than any other way. The Main Agricultural Bulletin No. 179 gives some valuable information on this subject, and can be had for the asking. Sprouting simply makes the grain succulent, there being no more food than in the whole grain, but in better form.

This bulletin also contains details of a lice powder and a cheap spray; however, crude oil with 5 per cent carbolic acid makes as good spray as any you can get. It is better to cut your green food and feed it than to allow the fowls to run out on it, unless allowed to run on it for a few hours only each day.

There is no best grain or grain product. Experiments have proven that just as good results can be obtained from barley as from wheat, and equally as good from corn. When a generous mash is fed, equally good results are obtained from either of the grains. This is of particular value just now, because barley is cheap, and should give just as good results, because nearly alike.

If fowls are accustomed to wheat, and will not eat barley, it only shows they are creatures of habit, and as variety is the spice of life, you will find a varied diet will give better results. Grain alone will not make a profitable food, having too little protein, and it is therefore necessary to feed a mash. There is no best mash, but you should know what the mash contains, and be sure none of the ingredients are injurious. Barley meal is one of the best ingredients. Ordinary barley mashes have the hulls removed, and unless the husks are removed you will have crop-bound fowls. In taking out the husks you take out a good portion of the bran. One of the best ingredients for the mash is bran.

Experiments show organic phosphorus compounds are what make it especially valuable as food. Corn meal contains a small amount of protein, but contains a great deal of phosphorus. Fowls need this phosphorus for bone and shell. When both fowl and eggs are desired, there is very little difference between them, and that is why you should use the same feed to grow fowl as for eggs.

Water not fit for human consumption is not fit for poultry, and the same applies to the container. Of the grains, corn is very rich in nitrogen, and if cheap enough should be used, because it contains 25 per cent protein. Another good meal is bean meal, being twice as rich as other grains. Soy bean meal contains 40 per cent protein, and other meals can be used and are good. Oil cake meal makes a good addition to your mash, but a great deal depends upon the price. Use that which is cheapest, providing it contains nothing injurious. Cocoanut meal is an excellent feed when fresh, but is sometimes rancid. Cocoanut meal forms an extremely desirable addition to the mash; by adding hot water, it will readily mix with the ground meals. Linseed meal does not mix well, but is 50 per cent richer, and also cheaper. The richest meal is cottonseed, and that has been used extensively, but not to any extent for growing chicks. It is sometimes necessary to use one or more of these meals to balance up with. You must get nitrogen.

Animal protein has been proven necessary if good resulis are expected. The best form is fresh meat, but as it cannot always be obtained at reasonable cost, the best substitute is dry beef scrap. There are a good many samples of beef scrap on the market which had better not be used. Beef scrap should mean meat, not hair or bone. The pure food law covers not only food for human, but animal consumption as well, so you can expect to receive what is paid for. By examining the meat scrap closely you can detect any undesirable material, and if there is much hair or bone in the scrap you should not take it. Many of these materials are rich in nitrogen, but the fowls cannot absorb it. Concentrated soup the fowls cannot use, nor beef extracts. Some of these are stimulants, but not food.

Milk, if granulated and powdered, gives just as good results as meat, especially for young fowls. The next best thing is skim milk. Cottage cheese is practically the same as fresh meat, and is a very excellent way to feed skim milk. You must not force fowls to the extent that their digestive organs will be impaired.

Proprietary foods should not be used extensively; some are good, and others not so good. You can make up your own food, and just as good, if proper care is used in its preparation. It is always desirable to know the ingredients. Manufacturers sometimes use one thing, and sometimes another, so that you cannot know the contents of the food. Rice meal and rice bran sometimes contain 40 per cent ash. Cottonseed meal at times is found to contain 26 per cent protein instead of 46 per cent as it should. Oats bring good results when fed to young fowls. Alfalfa meal should contain at least 17 per cent protein, but is found actually to contain but 13 per cent in many samples. Dry blood is not reported on favorably, although some feed with good results. First-class beef scrap is a great deal better. All blood contains a great deal of waste matter, averaging about 84 per cent.

A little salt will give good results, but only in the same proportion as for human food. Pepper the same; fowls like it.

Rolled barley should be fed as a

rain, scattered broadcast. Ground one is an excellent ingredient, fed with less work and just as good or etter results by fixing a trough to ll once or twice a week, and protect- d so that there will be no waste. Cornell Bulletin 282 gives seven methods of feeding young chicks, and t would be well to obtain a copy. Green bone is best; lean meat better han dry scrap; fat is not good, and will advance fat in fowls. The mash ou can get the cheapest, of those hown in experiment bulletin, is the est. Buy chick feed which contains nly grain, no charcoal nor grit, and ny prepared meat scrap should be ept out, so that you can feed what ou want and know the amount. Any hange in feed is bad unless made radually.

There will be a new bulletin published by the California Experiment Station which will be put out in about one month, and will contain a formula for chick feed. This bulletin can be had upon application. Fresh blood is not worth half as much as fresh meat.

ABOUT INCUBATORS.

As soon as a man becomes interested in the breeding of poultry, he will, soner or later, come to the conclusion that successful hatching of the eggs cannot well be done or the business extended very greatly without the aid of the modern incubator. There are a number of reasons for this demand, and chiefest among them is that early in the season eggs may be plenty, but broody hens scarce, and this is particularly so here in the northern states, where the spring season sets in rather late. If the breeder waits till broody hens are plentiful, he might have chicks enough as the season advances, but as the early fall approaches, the late hatched chicks will not mature like the early hatched ones, and this, of course, is serious both to the market poultryman as well as the fancier, as in the case of the first, he must have his chicks out early so as to have them mature to good size when the market is good and to get his pullets out in time for early fall laying, and the latter not only finds the fall laying of importance, but size even more so, as the birds bred for exhibition would be seriously handicapped without the Standard demand in this respect.

Then a number of setting hens and their care during the time of hatching takes considerable time, more than the busy poultryman can well spare, and with more or less loss from broken eggs and hens leaving their nests. We cannot help but feel that though the incubator is not perfect in its construction and incubating power, it is a great time and money-saver, and will, with ordinary care, and a fair amount of common sense in the operator, give as good results, with less care and friction and consequent loss, than by using hens for incubation. We know that a few of the old-time poultrymen still have a strong prejudice against the incubator, for the reason that they think the stock hatched in an incubator is less strong and vigorous than what is hatched by hens, but this has been so fully contradicted by experience, that it hardly needs mention.

Why does the incubator fail in some hands more than others? I might answer this question by one word, and that is "fussing," which includes a good many reasons why some operators fail in succeeding with even the very best incubator on the market. Some people are everlastingly fussing with one thing or another, making an improvement (so-called) here, and another there, until the makers of that same incubator would be absolutely bewildered to understand that even the very slightest success could be obtained. The incubator was made for the purpose of hatching eggs, if those eggs are fertile—not to put brains into the operator, though he generally thinks he has more of the gray matter in place than the inventor of the incubator himself, and when the machine fails, it is always the incubator and the man who made it who are to blame, never the man who did not know enough to follow instructions. Common sense would teach the average intelligence that the inventor of the machine and the firm who send it out have experimented and tested their machines so they will give the highest percentage of usefulness in the incubation and hatching of eggs, if the instructions sent with the machine are followed.

Of course there are rules subject to change according to locality and time of year the incubator is operated, but this is generally stated in the instructions. It is the statement so often made by the inexperienced that causes the most trouble and loss. Sometimes even those supposed to know what they are about will make statements that the experience of any incubator operator would laugh to scorn, simply because he knows better. We have frequently seen it stated, and it is repeated year after year, and which has frequently caused the loss of more than one batch of eggs, and that is simply because in the critical moment they were disturbed by the impatient and inexperienced operator of an incubator with which he is making his first trial. Here is the oft repeated story: "A strong and well ripened embryo is ready for exclusion by the end of the twentieth day, and should be out and dry by the beginning of the twenty-first day." Here we have an unqualified statement that is a complete fallacy if applied to all breeds and under all conditions. Men of practical experience know that the age of eggs used in the incubator has a great deal to do with the length of time it takes to hatch them. Eggs two or three weeks old will not pip the shell until the very last of the twenty-first day, and sometimes longer. So, the heavier breeds, like the Cochins, Plymouth Rocks, etc., will take the full time to successful exclusion of the chick. And why is this? Well, I don't really know; but fact is fact, and is a great deal better for the successful running of an incubator than theory. I read not long since, of a man who at the end of the twenty-first day smashed a whole tray full of live and strong eggs because no sign of pipping had occurred. If this man had known the fact that early in the season one or two more days would have been necessary to complete the hatch, especially as he had run the incubator in a very cold place, and turned them, and cooled them in a very low temperature, such a rash act would have been prevented. I have taken off as fine hatches of chicks as anyone would wish to see, that with a correct hatching temperature had run well into the twenty-second and even the twenty-third day—chicks that grew apace and matured into fine stock, and notwithstanding all the talk that chicks not excluded on time are not worth while raising.

Again we have often heard it said, "A chick that has got to be helped out of the shell is no good." There are, however, circumstances and

JUBILEE INCUBATOR CO., Sunnyvale, SantaClara Co., Cal.

weather conditions where help becomes imperative and ought to be rendered. There have been seasons when it seemed almost impossible to hatch an egg successfully in the incubators, and under the hens as well, and it was not the fault of the breeding stock, as the eggs sent away from home hatched splendidly for others. It seemed that one-half would stick in the shell for no reason whatever, or at least, no known reason. Some of them more than half done with cutting the shell could make no further turn, and there they were imprisoned. I have at times noticed chicks by sheer force to burst the shell, and part of the shell glued to their back, and not because of any abnormal conditions of the fluids contained in the eggs, which still sometimes cause this condition, but only in one or two eggs out of a whole hatch. Now, some will say that this condition was caused because moisture in a sufficient amount was lacking, but this is not the reason, as the same condition would prevail in both incubators, one with applied moisture and one without it. I have sometimes thought that the shell might have lacked the qualities which make it porous enough to absorb the moisture, but it seems to me that would have hindered the embryo from developing as well. But whatever the cause is, it would have been sheer foolishness to have left those chicks to perish, which, without help, would have been the result. Simply clear the machine of the chicks already hatched, and the shells, and immerse the remaining eggs in water at a temperature of 105 degrees, putting them back in the machine dripping wet, and in a short time a lot of them will hatch.

Sometimes a chick will make a wrong turn in the shell and imprison itself, and this takes place in almost every hatch. When clearing out the machine, I have given such unfortunates a little help by locating the trouble under a strong light, and then picking the shell where the head is located, which is generally near the small end, and in this way saved a few that would otherwise have perished. All this may happen to good strong chicks; in fact, they are generally pretty robust and therefore yell for help.

Some of the essentials for a good strong incubator hatch is to have robust, vigorous stock to begin with, birds that will produce eggs with a germ that has a kick in it. Any amount of failure to succeed with an incubator is due to the stock, as there are a number of breeds that have been inbred for generations to such an extent that the stock has been weakened, and it is almost impossible to make their eggs hatch under hens, and it is simply to court complete failure to try them in an incubator, however good the make of it. But where these conditions do not prevail, the incubator at all times of the year will prove satisfactory, and give complete success even in the hands of an inexperienced operator, providing he follows directions, and has some common sense, without which even the directions would be misunderstood. I have, however, known persons who could not get results from an incubator, but their disposition and make-up was the direct cause of the failure.—American Poultry Journal.

IN THE RICH FIELDS OF SAN JOAQUIN COUNTY. Courtesy San Joaquin Co. C. of C.

SUCCESSFUL MATINGS.

The fertility of the eggs from each pen mated is, of course, of great moment, and therefore we will give this matter our first consideration, for however good the birds may be in feather they cannot reproduce themselves except the eggs are full of vitality, for the vitality in the germ is the foundation strength of the growing stock, and the beginning of all successful life both in man and animal.

Now the fertility of eggs depends chiefly on two conditions being observed and neither one can be disregarded: the stock birds must be in good health and the number of females allowed to each male not more than he can manage and keep himself in sexual vigor.

The number of hens that any cock bird may be allowed naturally depends upon the age and vigorous propensities of the bird, and whether he is on free range or in confinement, whether he is of an active or sluggish dispositioned breed and the time of the year in which he is mated to his companions.

For instance, a Leghorn male will very frequently give proper attention to fifteen females in a fair-sized pen, where a Cochin would often times produce a number of infertile eggs mated to half of that number, and if the Leghorn was on free range when spring opens up he would manage from twenty to thirty without the slightest trouble.

To give an exact number for any breed is worse than useless and misleading, but as most of our matings are made up for best results, both as to fertility and strength of the product hatched from the eggs, much must depend on observation, for it is pretty nearly as bad to undermate as to overmate, for in the first case a strong male bird will worry the females till he gets them down on the legs, and in the second instance he will weaken himself.

It is not often mentioned that a male may run with fifty females and yet in some such cases a good proportion of the eggs will be fertile, because he will only give attention to the few hens in the flock that are productive, and the hens themselves will keep out of his way. My reason for mentioning this is because oftentimes the small breeder has only one splendid male bird, and he would like to mate him to as many females as possible and get as many fertile eggs as he can.

Now, early in the season it is not likely that all the females will be laying, but that they will come on, as is always the case, little by little, and at this time it will cause no trouble if a strong male is mated to a greater number of females than is usual, as his attentions will only be given to the layers.

If the whole flock is shelling out eggs as fast as they can, this course cannot be followed, but that is rather the exception than the rule during the months of February and March.

As to health, the birds must be in full possession of it, as no results can be expected where the breeding stock lacks in this respect. The females should be in a good active condition, in good flesh, but not fat; a flock of over-fed lazy hens will not be likely to fill the egg basket, and after having taken on a surplus of fatty matter it is hard to get rid of, as it will cause inactivity, which is sure death to the successful establishment of the breeding pen.

Some of the smaller breeds do not get fat. No matter how much is fed them their active disposition will hinder that condition, but all the larger breeds, including all the American varieties, will fatten easily if over-fed, and as a consequence become useless as breeders. When the stock is in full lay they will not fatten readily if the proper food is given them. The period which needs the most care in this respect is when the stock is ready to lay, yet lingers and sings, as a pullet sometimes will, for several weeks before she lays the first egg.

Too much attention cannot be given to the matter of plenty of good water and green food. I believe that not

PETALUMA INCUBATORS AND BROODERS

the leaders. Principle, Construction, and Results compel the admission that there is none to equal them. There is a difference between chicks just hatched and those "well hatched."

There is a reason why users of Petaluma Incubators accord to them genuine supremacy. There is a reason why with far less advertising more Petaluma Incubators and Brooders are sold than ever before.

No other Incubator in the world has a hatching record to equal the Petaluma.

MODEL POULTRY FARM Irvington, Alameda County, California.

only the number of eggs laid, but the fertility of them, largely depends on providing well for the birds in this respect, and observations show how important this matter is.

The largest egg yield is given us early in the spring. Now, all we have to do is to watch our birds, and we will find that they will leave their usual rations and fill themselves full with the first spears of the growing grass, which simply shows that their system craves this food more than any other, however good it may be.

Cabbage is not too dear at any price, as it provides well the craving of nature for green food, and there is nothing better. A few apples will be relished and provide a change. Beets, turnips, carrots, in fact every thing in the way of eatable roots will answer, but the green leaf of the cabbage and the early spears of the grass are most preferred.

Soft food we deprecate in the breeding pen. It is not conducive to exercise and impairs digestion more or less, and is a means of forcing for eggs, which, of course, should never be done where the eggs are to be used for hatching. A natural coming into laying by the females will, when they get started, induce a steady supply, and they will be strongly fertile, with a germ that has a kick in it, and which will produce a chick that comes into the world with a good intention to live and begin life without that tired feeling that generally ends fatally.

Much complaint is heard every season from persons buying eggs for hatching that they have had very poor results, or none at all, which is generally the cause of improper care of the eggs, if previous condition of the stock is all right.

A suitable place should be selected, not too warm and not too cold. If very warm during the day and very cold at night is the condition under which the eggs for hatching are kept, the result most likely will be addled eggs when put under the hen or in the incubator.

An even temperature of from 40 to 50 degrees is the most suitable in which to store eggs for any length of time that are to be used for hatching. and if early in the season eggs should be collected often, in fact before they turn cold, as they chill easily early in the season when it is still freezing weather. Every year we have marked eggs that were very cold to touch with a C, which stood for chilled, and up to date none of them, though the germ would start, ever produced a chick at hatching time.

We have already hinted that close housing is not desirable, even though in some parts of the country cold weather persists during February and March. Give an abundance of fresh air, but remember that fresh air is not drafts going from one end of the house to the other. A yard of strong vigorous birds will want to get out on the coldest day, and they will do very much better for it. Coddling is not conducive to strong fertility, as all it does is to engender laziness, and this last is simply the beginning of the end, the end of eggs in any great numbers, and those gotten will not produce strong chicks.

A hen which has no more ambition than to stand around and shiver with her feathers on end when she ought to be taken out of the pen and kept by herself, and given no other food than she will dig good and hard to get, and this treatment will reduce the flesh, or fat, I should say, and generally succeeds in making a hustler out of a good-for-nothing, and yet the hen is not always to blame for they are very much like humanity in getting as much as they can and for as little hard labor as they can, and many a flock of otherwise good fowls has been made useless by overfeeding and coddling.

Open up the windows, give air, plenty of it. When you do, there will be no wet walls in the poultry house, nor a lot of sneezing hens or hangarounds, but birds that will go singing to their work and look health and activity all over, and that means plenty of eggs, and fertile eggs, and strong chicks.

Whatever system of feeding is employed stick to it, providing it contains all the necessary nutrients for egg production, and if the hens are laying pretty well, whatever you do don't shift from one kind of feeding to another, for you will simply stop the hens from laying.

They do not take readily to a radical change of food, and though I believe in a variety, this can be done by adding a little today and some other little tomorrow, but if you want to try the "dry feed plan" begin it with the chickens and not with a lot of hens, for they will not take to it readily and will certainly leave you without eggs, for a spell at least.

There are so many poultrymen so fond of trying things, but it is unwise to try anything except we try it in the right way, and when eggs are wanted for hatching, and lots of them, that certainly is not the time for experimentation.

As to the ages of the birds, we have something to say which is of vital importance if continued success is to be maintained: Young and immature birds are not fit to breed from. There is no power on earth that can retain the strength, size and vigor in any breed if a succession of cockerel and pullet matings is resorted to.

I always maintained that a pullet would make a breeder if she was hatched late in February or the first day of March of the previous season, that is, when she is a full year old, but pullets younger than that make poor breeders, and how frequently these little runts are used, hatched late and used early, and all the care, and all the choice feeding you may resort to will never make matters right.

Young full-sized hens, one and two years of age, will give results both as to feather and egg production which younger birds will seldom if ever do.

The same holds good with the male bird. Nothing less than a full year old, and not then, except he is well furnished with hackles and sickles, and at least a half spur, the emblems of sexual maturity.—Successful Poultry Journal.

LOOK AT THIS PICTURE

AND THEN AT THIS

Which is Your Place?

Are you feeding Any Old Chick Food, or are you feeding Coulson's Special Chick Food?

It is of vital importance to the life of your chicks that they have a good start. You cannot handicap them by poor food and expect them to grow to be good layers or good, marketable fowls. START RIGHT and your profits will be large.

Almost the one difficulty of the poultry business is the preservation of chicks. Their digestive organs require a certain kind of food and in the right proportion. When you vary from the demands and abilities of nature you are walking on a hazardous road. You are inviting a loss.

Our Chick Food furnishes the vital element of young strength, gives vigor to the body and carries the little creatures through the first six weeks of their lives—a period in which they are most susceptible to bowel trouble, colds and disease.

Follow this with Coulson's Egg Food and Coulson's Scratch Food. Your chickens will develop into strong, healthy birds and bring you a good profit.

We also carry a complete line of poultry supplies, including Incubators, Brooders, Remedies, Insecticides, etc.

You can buy our products from any reliable dealer. Insist on getting our goods if you want the best for your money.

Irrigation and Forestry

THE CREOSOTING OF FENCE POSTS.

The vast number of fence posts used in the United States every year, and the growing scarcity of hard, durable post timber such as chestnut, black walnut and white oak, as well as the increasing demand for this more valuable timber for other purposes, have in recent years made it more and more necessary for farmers to depend upon softer and more quickly decaying wood for fencing purposes.

As a means of increasing the life of the pine, willow, sycamore, cottonwood and other kinds of soft fence post wood, many up-to-date farmers are employing creosote and other preservative oils with good results. It has been found that the resistance of all treated posts to decay is alike, regardless of the wood used. A pine post treated with creosote will last as long as a chestnut post untreated, which means that it will be good twenty years after being set. And these inferior, soft woods take treatment better than the harder woods, because the soft woods generally have a deeper sapwood, which readily absorbs the preservative oil. This applies especially to water oak, maple, quaking aspen, willow, sycamore and cottonwood.

The best preservative for wood is creosote, or dead oil of coal tar. Another advantage is that the price is reasonable. It can be purchased by the barrel in almost any large city of the United States, but is cheaper in cities near coal mines, or where illuminating gas is being manufactured, when the price may be as low as ten cents per gallon. To obtain creosote the coal is subjected to high heat, without the presence of sufficient air to promote combustion. This process gives two main products—illuminating gas and coal tar. The latter is then distilled and separated into the light oils, the dead oils (creosote) and pitch. The heavier the grade of oil used for creosoting wood the better.

In applying this preservative treatment to fence posts the larger the boiler used the more economical will the process be, because you can treat more posts at a time, which is quite an item, for they should remain in the creosote from two to twelve hours. The boiler should have a flat bottom, with ten or twelve square feet of surface. If creosote is cheap and you wish to treat the entire post the boiler should be about six feet long and probably two and one-half or three feet wide. But very good results may be gained by treating only the butts to at least six inches above the surface of the ground, for it is, of course, much more important that the part coming in contact with the earth be heavily charged with the creosote. Then after the posts have thoroughly dried and are set, the remaining parts may be given a coat of hot creosote with a brush.

The creosote in the boiler or tank should be heated from 180 to 230 degrees F., and the posts should remain in this bath for two to eight hours, depending somewhat on the kind of wood treated, but more upon the dryness of the wood. The hotter the creosote, the further the oil will strike in, but the temperature should never be higher than 250 degrees F. Also the longer the posts remain in the boiler, the better the treatment will be, and the longer will be the life of the post after it is set. Where posts contain much sapwood the oil goes in deep, but heartwood does not absorb the preservative readily. Soft wood like pine, or porous woods like red oak and the poplars, can be treated more easily than dense woods like the oaks, and hence need not be left in the creosote for so long a time.

All the inner bark should first be removed, and after treatment the posts should be stood with the butts up, in order that the free oil may run down over the small end.

The top of the posts should be cut slanting, preferably with an ax, and if only the butts are treated the top of the posts, after being set, should be given two good coats of the hot creosote, or even linseed oil containing a little white paint, in order to form a surface on top of the post impervious to moisture. This is especially important in the case of large grained woods like red oak, for it is here that the moisture gets into the untreated post and starts it to decaying. When posts are cut with a saw the pitch should be still greater.

The top brush painting should be done during warm weather. If done during cold weather the oil hardens on the surface of the post without striking in.

If creosote is expensive, and you cannot afford to treat the tops by brush painting, it will help considerably to give them a heavy coat of linseed oil combined with a very little white paint, giving the top ends two or three coats. The posts should be treated and set in the ground only when thoroughly seasoned, and during dry weather. Wood dries faster in spring and summer, but is more apt to check or crack. The best time to cut fence posts is in the late autumn or early winter, and treat them in the late winter, giving the tops the brush painting on some warm, sunny afternoon.

It is estimated that it costs eighteen cents to buy and set an untreated pine fence post under ordinary conditions, and thirty-three cents for treated posts. The untreated post will last about four years, making the annual cost about five cents, while the treated pine will last at least twenty years, at an annual cost per post of only three cents, so at the end of twenty years you will have saved forty cents on each post by the creosoting process. —Pacific Homestead.

Irrigation consists in diverting water from a natural stream by either ditch or canal and causing it to flow or spread over the land at stated periods.

Irrigation was probably originally resorted to by communities in which people were confined to prescribed limits and who learned the beneficial use of water. Under irrigation there is no failure of crops, and, upon investigation, it is found that it was extensively practiced in times of remote antiquity, as, for instance, in Egypt, where it was practiced over two thousand years before Christ, and the remains of great systems of canals and artificial lakes are found today, showing that irrigation was at one time fully understood, not only in Egypt at that remote period, but in India and China as well, and among the people

of these countries, who have not entirely lost their ancient prosperity, such works still exist in almost their original form.

In many parts of the world the necessity for irrigation is so strongly felt that it is resorted to by comparatively rude tribes, such as was found by the Spaniards to be the case among the Pueblo Indians in Mexico, who were irrigating the thirsty soil as their forefathers had done for centuries before them, and their descendants are still doing so today.

In the desert wastes of the Southwest, Spanish settlements sprang up and were maintained by means of irrigation. There are a few ditches in Southern New Mexico which have an unbroken record of use for over three hundred years. Some plants require a great abundance of water; for example, rice, which is the principal food of many people of the world, especially those of Asia.

Irrigation prevails in the southern portion of Europe, and was extensively practiced by the Romans, and today the greater part of Spain and Italy and the southern part of France are almost entirely subject to irrigation. It is estimated that the river Po irrigates 1,600,000 acres alone.

Irrigation and the conservation of the water of the streams has been and is one of the great problems confronting the people of the arid and semi-arid countries, and under proper attention being given to these problems the most densely populated sections of the globe have existed and do exist.

Agriculture under irrigation in the arid and semi-arid regions of the United States is most favorable as to temperature and sunshine. The soil brings forth crops quickly and abundantly. The arid region of the United States extends from the lower Rio Grande river along the base of the Rocky Mountains and as far north as Edmonton, Canada, and along as much as one-half the western Rocky Mountain base. This region of the United States is estimated to comprise over one and a quarter millions of square miles of territory, and the total reclaimable area in the United States has been estimated by Major Powell as sufficient to form eight states the size of Indiana.

A great deal of attention has been given irrigation in the intermountain country during the past twenty years. Extensive works have been constructed, many are being built, and others are under contemplation, and it may be said that those already completed and those building are largely copied from the ancient works of the same nature in Europe and Asia.

The settlement of Utah in 1849 and the Greeley colony of Colorado were the first people of Anglo-Saxon extraction who adopted this mode of agriculture in the Middle West.

Only during the past few years has any thought been given to the storage of water. In fact, the question of the storage of water is in about as immature a condition right now as was farming here in 1880.—Irrigation Journal.

The water supply is one of the first subjects to be considered by a prospective buyer of irrigated land. That generally comes from the natural watershed of the mountains. The supply depends largely on the snow and the moisture-holding properties of the forests. If the underbrush and grass become wasted for any reason—fire or over-grazing—the snow will disappear early in the spring, and a scarcity of water will follow later in the season. If there is no water in the streams of nature, the owners of irrigation canals cannot deliver water to the farmers.

Deep Well Pumping For Irrigation.

The past season has demonstrated more than ever the practicability and superiority of the Pomona Deep Well Pumps. It is fully proven that it is possible to lift large quantities of water from very deep wells with a surprisingly small amount of power. It has usually been considered that a plunger pump is only good for a 35-inch stream on a lift of say 200 feet, but the Pomona Manufacturing Company have demonstrated that it is no longer necessary to use a centrifugal pump, with its wasteful usage of power, to get a large quantity of water out of the ground, as this company is manufacturing extra large size cylinders including 12, 13, 14 and 16 inches in diameter, and capable of lifting from 50 to 100 miner's inches of water. Not only that, but they are prepared to go down after it to depths of 300 and 400 feet if necessary.

They have one plant at Claremont where the water stands 390 feet below the surface and the pump has a total lift of 450 feet, delivering 45 miner's inches of water with 60 H. P. on the motor, and doing it easily. There is another plant in Ontario lifting 60 miner's inches 300 feet with a 60 H. P. engine.

The parts below the surface have been so perfected that they are perfectly reliable and are giving as little trouble as it is possible for a machine to do. Other pump makers, noting the wonderful success of the Pomona Pumps, are trying to imitate them, promising something just as good, but they are only imitators and have not the knowledge or ability to make their claims good.

The Pomona Manufacturing Company has a large plant at Pomona, the only one in Southern California, devoted almost exclusively to manufacturing Plunger Pumps. They are a reliable establishment and are here to stay, to make good their guarantees and to supply your wants in the way of extras or assistance. Their machines and apparatus have been tried out and their value fully demonstrated.

Anyone needing pumping machinery should send to them for catalogs, or visit them in person.

Ground Squirrel Eradication.

Kindly inform me how to proceed after land owners have refused to eradicate squirrels. They now refuse to do anything.—Reader, Lindsay.

This question was submitted to Surgeon Rupert Blue of the Marine Hospital Service and he writes in effect that "Delinquents should be reported to the Secretary of the State Board of Health at Sacramento. After the counties have been organized and the inspection service established, complaints may be made direct to the chief inspector at the county seat."

State Commissioner Jeffrey writes more fully as follows:

"The squirrel law is at present in a very chaotic condition. In the first place nearly all the old laws requiring the extirpation of squirrels in certain counties named in the legislative acts have been repealed, and in those counties in which the legislature has not repealed the law it is a dead letter. There is a general power delegated to the board of supervisors of the state authorizing these boards to exterminate these pests, but it is rarely if ever invoked. This is the law under which Santa Clara and two or three other counties appointed the so-called 'county entomologist,' as the general power referred to above included insect pests, as well as squirrels, gophers, etc.

"It is true then that all our old laws relating to the squirrel pest are either obsolete, repealed or left to the supervisors to initiate enforcement. There was then, up to March 13, 1909, no effective power to whom one could appeal for enforcing the destruction of squirrels, and the law of 1909, I fear, will be as abortive as previous measures, though it will have behind it some power from the State Board of Health, but not enough to compel observance. Briefly, the new law declares it to be the duty of every one harboring squirrels, rats, mice, gophers or ground squirrels to destroy these pests; it authorizes state and county boards of health or their inspectors to enter all premises for the purpose of determining if the pests abound; the boards of supervisors or city councils, when they deem it necessary for the preservation of health or the protection of crops, 'may' by resolution appropriate money with which to buy traps or poisons, and with which to employ inspectors and otherwise prosecute the extermination of these pests, all under supervision of the board of health; whenever persons harboring these animal pests shall refuse to abate these nuisances the inspectors shall cause the work to be done and the expense shall be a charge against the county or the city, and the expense may be recovered by lien as is done in the extermination of fruit pests.

"If the State Board of Health carries out its present plans the law will not be abortive, though no enforcement of the act has as yet been attempted. The State Board has already requested the supervisors of the state to fully notify all interested parties that the law will be enforced; expert advice as to the best means of killing squirrels will be given by the federal and state health authorities; property owners have been given time expiring 31st January this year in which to exterminate; upon that date all property owners who have not exterminated the pests will be warned by the supervisors or councilmen and given one month in which to complete the task; on February 1 final inspection will begin, and all property found infested will be condemned as orchard infection is now condemned under another law; the final work upon these properties will be done by the county or state health officials and made a lien collectable as all liens are collectable.

"In answer to your question as to whom complaint shall be made by one whose neighbors have not complied with the law, the complaint should be filed with the State Board of Health, at Sacramento, or with any county health officer under the jurisdiction of the State Board."

Eucalyptus for Malaria.

If it is true that planting eucalyptus trees around buildings will prevent malaria, what kind is best? Also which is best for posts and fuel?—New Subscriber, Patterson.

It is not true that eucalypts prevent malaria. Our scientists inform us that malaria is caused by infection through bites of a certain mosquito, and unless the eucalypts absorb moisture from stagnant water in which the mosquitoes might breed, they would be of no benefit. There is a very general opinion, however, that eucalypts do aid in creating healthful conditions. We would not plant too close to the house where the shade would be too dense. So far as we have heard expression, the blue gum is given the preference. It is the richest in eucalyptus oil, which is a perfect antiseptic. For fuel the blue gum is also to be preferred, principally because of its rapid growth. In your section of the San Joaquin Valley it is possible the temperature might be too low for the blue gums to do well. In such a case we would plant the red gum, rostrata. Neither of these varieties is ideal for posts, but if cut in the fall and allowed to season, then treated with creosote, they do very well.

Poison for Ground Squirrels.

What is the best way to kill ground squirrels? Will they eat wheat soaked in strychnine?—Subscriber, Patterson.

The best treatment for ground squirrels may be found described on page 584 of the Cultivator of December 8th. This article gives the formula by the Public Health and Marine Hospital Service.

Hens vs. Ducks.

Which is considered most profitable, raising hens for eggs or ducks for market? What strain of ducks is best for eggs and how do they compare with a laying strain of hens as to number of eggs per season?—A. W. M., Durham, Butte Co.

The profit in either case would depend upon the market and other conditions, more perhaps upon the preferences of the man or woman entering into the business, but in a general way we would say that the duck business would be more satisfactory where the ranch was near a large market. It would seem to me that

Butte county was too far removed to promise greatest success. Express charges and loss in transit would handicap the producer. This would not be so pronounced with shipping of eggs. The best laying strain of ducks is the Indian Runner, sometimes called the Leghorns of the duck family. We do not think they will average the number of eggs that the best hens will, and some markets discount them, though they are a large egg.

Rheumatism.

I have a hen about one year old that seems unable to use her legs. She eats well and seems fairly well. She started in by stumbling about two weeks ago, but now she can hardly stand at all. I have others that are all right. I feed bran with table scraps in the morning and wheat or grain at night. They have plenty of green food. If you can assist me with information I will be very much obliged.—H. T. B., Los Angeles.

Hen is suffering from rheumatism, and Mrs. Basley recommends a liniment composed of one teacup turpentine, one of vinegar and a tablespoon of saltpeter. A neighbor has used it for a hen suffering as yours does, and she was helped.—Mrs. Frank Metcalf.

Barrenness.

We have purhcased a heifer calf from a most valuable cow, and we had hoped to raise her and keep her for our own use. The calf is a twin, and we are told she will never become fresh.—Subscriber, Kingsburg.

This belief in the barrenness of twins seems to be general, but we have heard old stock growers say that they would give much to know of one authentic case where twins failed to make good producing cows simply because of that fact. Of course, any animal may be so affected, and it is possible that one of twins might be, the same as any other animal.

Temperature for Guavas.

Kindly let me know how low a temperature guavas will stand. Where may plants be bought?—Subscriber, Yucaipe.

The guava is a tropical fruit, and will stand but little frost; when the plants are young, practically none—that is, they should be protected for the first year or two. After they are well established they will stand practically the same as an orange tree. We have known of the plants doing fairly well in sections where the temperature has been known to go as low as fourteen degrees, but such a condition is not ideal for the plant. Your local nurseryman should be able to supply you. If not, apply to nurserymen advertising in The Cultivator.

Alfalfa for Poultry.

Please give balanced ration for poultry in which alfalfa meal forms a part. Is it desirable feed for poultry?—Subscriber.

From the circular of an alfalfa meal manufacturer, we give the following formula for laying hens. Alfalfa meal is rich in protein, and does make an economical feed in California:

5 lbs. alfalfa meal (coarse).
4 lbs. barley (rolled).
7 lbs. wheat (cracked).
1 lb. meat meal.
2 lbs. cocoanut oilcake meal.

Olive Cuttings.

Please give me directions for starting olives from cuttings. Can cuttings in nursery row be put out in spring?—Subscriber, Fresno.

There are two forms of cuttings from olives. The tender herbaceous tips should be taken in the spring-time, when the trees are growing thriftily. These are cut a couple of inches or longer, and buried in sand. With under heat in the glass house they will soon granulate and send out little rootlets, when they may be planted in nursery row. Then, after one summer's growth in nursery row, they may be set in orchard form, but many prefer them to have two seasons' growth. The other form of cutting is the hardened wood, which may be cut at this time of the year. Such cuttings may be the size of a lead pencil or larger, and ten to fourteen inches long. Bury two-thirds of cutting in sandy soil, rows far enough apart to allow of cultivation, and a few inches apart in the row. One or two summers' growth in the nursery row will precede orchard planting.

Veterinary

Answers in this column by Dr. Fred G. Matthews, are without charge. For immediate mail answer remit $1.00. In writing questions give full symptoms or particulars of injury of animal.

Swelling—Brittle Hoof.

My horse has a swelling on his chest. There is a small scratch on the surface. Probably bruised by reaching over the manger. Another horse has brittle hoofs.—Subscriber, Delano.

Change to a stall where the breast will not come in contact with the manger while the horse is eating. Horses sometimes injure the windpipe or the breast by resting the parts against a high manger. Paint the swollen part with tincture of iodine three days in succession, skip three days and repeat. Nothing is better for brittle hoofs than to allow the horse to go without shoes for a few weeks in wet weather. If this is not practicable, a good hoof liniment may be made by mixing melted lard four parts with pine tar one part. After cleaning, paint the hoof—shell and bottom—every third day with the ointment.

Scirrhus Cord.

Several shoats have tumors as large as cocoanuts which appeared after castration. They are not ruptures, though they have that appearance. What is the cause, cure and preventive, if there is any?—Subscriber, Kerman.

Examine each enlargement carefully by having an assistant elevate the rear end of the pig while you press upon the tumor with the thumbs. If the tumor disappears, wholly or in part, it is probably a rupture, but if it remains hard and prominent, it is a disease of the cord due to the growth of a mould-like microbe in the castration wound. In that instance your only recourse would be to remove the tumors by surgical operation. Since you have a number of these cases, and also considering the liability of rupture complications, it would be well to employ a veterinary surgeon to do the operating.

Castration performed under proper precautions of cleanliness and with the use of suitable antiseptics, is seldom followed by such growths. Either the castration operations were improperly performed or the infection exists in abundance on your premises.

It is reported that Santa Cruz county is beginning a new era of tree planting which local nurserymen are planning to supply. One nurseryman is now grafting 175,000 seedlings.

EVERYBODY KNOWS

That the "SUCCESS" Incubators and Brooders are sold for many dollars less than other companies can afford to sell at.

THE REASON? We do not own a $50,000 plant; we hire no useless office officials, everybody works, we sell on a close profit, buy everything for spot cash, own the Pioneer Hatchery Company, the largest hatchery concern of its kind in the world. Own our own building, pay no rent, have no partners and have to pay no dividends to any one.

WE SELL DIRECT to you at wholesale prices. We do not sell on credit to any concern whatsoever. Can redwood be shipped east and then reshipped back again to California and sold to you in Incubators unless they make a big profit on the deal? Think it over. I am willing to sell at a close price. I also pay the freight. Every Incubator I sell is sold on our

FREE TRIAL OFFER—30, 60 or 90 days.

Get the 1911 illustrated book today; contains 48 pages, and the most interesting book of its kind ever written.

EXPERIENCE. We certainly know how to make good Incubators; we incubate thousands and thousands of eggs year after year. Machines we offer are not new, untried experiments. I make four sizes: 60 Egg, $9.00; 130 Egg, $14.00; 360 Egg, $25.00; 612 Egg, $40.00.

I PAY THE FREIGHT.

THE LARGEST SALE OF INCUBATORS EVER MADE at one time to a customer in Los Angeles was made by us when we sold Carl Matson his large number of 612 egg size Success Incubators for his hatchery.

INVESTIGATION is all I ask. If my book can't show you plainly why I can sell you the best Incubator for the least money—then no harm is done.

FIRELESS BROODERS—75 Chick, $3.00; 150 Chick, $5.00; 150 OUTDOOR style, $6.50. We pay the freight.

Send for the book today. Send your neighbors' names.

"Let There be Light."

—PAT HENRY, before the battle of Bull Run.

We are not sure that our old friend Pat has been correctly quoted, neither do we know that he was anywhere near Bull Run during that memorial event, but we do know that every Rancher, Miner, Dairyman, Stableman and Teamster on the Pacific Coast should be in possession of at least one of our Vehicle Headlights, here illustrated.

There are times when a good, strong light is almost indispensable. It is needed around the barn, the thrasher, the harvester, on the gang-plow, on your wagon or buggy when driving over rough roads, the ranch, the mine or the dairy.

A Boesch Vehicle Headlight is worth a dozen ordinary hand lanterns. They are well made, strong and durable, each one is fitted with a highly polished silver plated parabolic reflector which concentrates the rays of light with remarkable brilliancy. The body is finished in a rich glossy black with polished brass trimmings, and for appearance it is first in order of handsome lamps. It embodies all our latest improvements, and for efficiency as a light producer it is without equal. This is the Headlight that caused the passing of the State Law prohibiting the hunting of wild ducks by artificial light. It is being used by nearly every Fire Department on the Coast and in many of the large Eastern cities.

Do not be led into buying a cheap, inferior lamp. It won't pay. This one is the result of forty-two years' experience in the business. It is home industry, and we guarantee satisfaction. It is made in 6, 8 and 12-inch sizes, measurements across the face.

We also manufacture many other styles of Headlights, Lamps, Lanterns, etc., too numerous to mention.

Write for Catalogue and full particulars of lamps or lanterns that you require.

Timely Ranch Suggestions

BROOM CORN.

The price of broom corn has been so high the past few years that it has become a very profitable crop to grow. Missouri has never produced a great deal of broom corn, but in a few counties it has been grown in considerable quantities. Henry county has usually held the banner in broom corn growing, having to her credit 1,375,000 pounds surplus in 1908 which was about 80 per cent of the crop in the state. Oklahoma is becoming one of the leading broom corn states and we reproduce for the benefit of our readers what the Oklahoma Station has to say about the best methods of growing and harvesting the crop:

"There are two recognized types of broom corn grown in Oklahoma: the dwarf and the standard.

Dwarf.

The dwarf is recommended for the general market and for Oklahoma conditions. It grows four to six feet high, with a brush twelve to twenty inches long. This type is best suited to the semi-arid region or to the upland of the broom corn section of the Southwest.

Standard.

The standard grows to a height of from seven to twelve feet and is adapted to the more productive soils such as bottom land.

Preparation of Seed Bed.

The soil should be plowed in the fall or early in the winter so that it will retain as much moisture as possible. About two weeks before planting the land should be disked and harrowed, and if necessary, harrowed a second time before planting. Broom corn is a good sod crop. It is very largely raised on the new land of Western Oklahoma and makes profitable yields.

Time.

Broom corn plants are very tender and make the most rapid growth in warm weather. They will not stand the cold of early spring like corn. The seed will rot before germinating, or if the plant germinates the growth will be retarded by continued cold. The climatic conditions of Oklahoma are such that planting in May will usually give the best results. When large areas are planted the most convenient way is to divide the field into sections of about ten acres each and plant at intervals of about a week. The crop demands prompt attention, and if this system of planting is followed, there is not so much danger of damage to the brush from rain, or becoming too ripe. In case farm hands are scarce the scarcity is not so keenly felt, for there is not a very large crop that demands attention within a period of a few days. A few hands can take care of comparatively large fields, and it is much more convenient than to plant the whole field on a single date.

Methods.

The method for planting is about the same as for kaffir. Plant in rows about three feet apart, and four to five inches apart in the row. The standard, due to its large growth, is planted in rows about three and a half feet apart.

Amount of Seed.

Selecting good seed is very important. Good seed should give a germination of 90 to 95 per cent and seed should not be used that falls much below this standard. By using seed that gives a germination test above 90 per cent, one bushel is sufficient to plant twenty acres, or two quarts of seed will plant an acre.

Cultivation.

The soil should be in good condition when seeded, then the cultivation should begin early and be repeated frequently to prevent the weeds from getting a start of the slow growing plants. A sharp tooth harrow is sometimes used just as the plants are coming up. After one good harrowing the field should receive about two cultivations of medium depth, then the rest of the cultivation should be shallow so as not to injure the root system. In this way the soil is finely pulverized, forming a dust blanket, which aids in the conservation of moisture.

Harvesting.

Broom corn is a crop that will not stand in the field without great damage when it is ready to harvest. It should be harvested just as the plants are coming into full bloom, or when the anthers are falling from the head.

Dwarf.

The head of the dwarf is inclosed in a sheath or "boot." It is more convenient to pull the head than to cut it, after which the boot is removed. The heads are usually pulled and piled in bunches along the row. The brush from three or four rows is piled together, and after drying for two or three days, is gathered and stacked in small ricks.

Standard.

Because of the greater height of the standard broom corn, it is necessary to bend the heads over to make them easy to cut. The stalks are bent at a height of about three feet. Two adjacent rows are bent diagonally across the intervening space so that the portion of the stalks above the sharp bend is supported in a horizontal position with the seed heads of one row extending about two feet beyond the opposite row. This method is called "tabling." One man can table as fast as two can cut. In cutting the operator walks along the space between the tables and cuts the heads six or eight inches below the attachment of the straws. The brush as cut is laid by handfuls upon every second table, making it very convenient for loading on a wagon.

Curing.

After drying, the brush should still retain the greenish color. To accomplish this it cannot be dried in the sun as it will be bleached to a light brown color. By curing in sheds the original green color can be retained to a large extent, and as a result the brush will command a much better price. The average time of drying is about thirty days. It is then thrashed and baled.

Yield and Value.

The average yield of the dwarf is about 1-5 ton an acre. The standard yields slightly more than the dwarf, the average being 1-3 of a ton to the acre.

The price per ton usually ranges from $50 for the lower grades and that damaged by the weather, to $200 for the very select. The 1910 quotations range from $140 to $190 a ton.

Feeding Value.

Sometimes the crop becomes ripe enough to form some grain which has a fair feeding value. Broom corn be-

longs to the non-saccharine group, and cha[illegible]good pasturage, if the ordinary prehandica[illegible]s are used. It is becoming more not b[illegible]tant as a forage, and the grower of [illegible]beginning to realize this and use d[illegible]as a forage crop after the brush tir[illegible]ds been removed.—Missouri Farmer.

BUYING ALFALFA SEED.

Farmers should take more than ordinary precautions in purchasing alfalfa seed to ascertain what they are getting. Alfalfa seed is subject to adulteration with cheaper seeds closely resembling it, and the great danger lies in the fact that with the adulterants some noxious weeds may be introduced, which will cause endless trouble and work in the future. It is almost impossible for the average individual to tell the differences between alfalfa, yellow trefoil, and sweet and red clover seeds. Alfalfa is frequently adulterated with these seeds by unscrupulous dealers, who, owing to the great demand for the seed, cannot resist the temptation. Good alfalfa seeds are of an obscure greenish or reddish yellow color, while the defective or immature seeds are usually brown and generally shriveled. The shape varies, but the majority of the seeds are kidney shaped.

Every farmer should know something about the history of the seed which he contemplates buying. It is an excellent idea to test the seed for vitality and purity; oftentimes seed is low in vitality and has as high as 15 to 25 per cent of weed seed. Such seed is usually offered at 10 to 15 per cent below market quotations and is likely to be more expensive than the higher priced, pure seed.

It is a simple matter to make a germination test. Count out 50 or 100 seeds of the kind to be tested and place them in a plate between two pieces of moistened flannel cloth. On a slip of paper record the variety, the number of seeds, and the date. Place the slip on the edge of the plate. Cover the whole with another plate, which is inverted. Keep the plate at room temperature for several days. Examine the seeds daily, and if the cloths become dry, sprinkle a little water on them. At the end of several days count the sprouted seeds, and from them determine what percentage of the whole number of seeds is good. —James D. Marshall, Colorado Agricultural College.

FLY CATCHERS.

When the government of Mexico decided to drain Lake Texcoco, in order to lessen the danger of floods during the rainy season, and also to get at the rich soda deposits in the bed of the lake, it sounded the doom of one of the queerest and most ancient industries in the New World, that of catching flies for market.

Since the days of the Aztec lords of Mexico, a small band of natives has made a comfortable living out of the business of supplying the canaries and other pet birds and fine poultry of the United States and Mexico with the delicacy of dry salted flies. Now the lake is drying up, the flies have disappeared, the birds are to go hungry and the fly catchers have abandoned their pleasant vocation for the drudgery of digging soda from the bottom of a smelly lake.

Catching flies for market on the shores of Lake Texcoco has been a profitable industry since the days of the Aztecs. Until recent years the annual production of dried insects was measured in tons, and until this year was sufficient to afford a means of livelihood to a small colony of native fly catchers.

These market flies are a little smaller than the ordinary house fly. Preserved in the natural salts, they were found to be an excellent food for caged birds and chickens, and hundreds of sacks were shipped annually to bird dealers in the United States and Germany.

The insects are caught in nets as they swarm near the lake's surface, killed by drowning in the water and immediately spread out on sheets to dry. After this simple curing process they are sacked up and are then ready for market.

The profession of fly catching and fly preserving has been handed down from father to son in a few families who have held a monopoly on the industry since the days of Netzahualcoyotl, when that monarch signed a treaty with the Casique Chimalpopoca of Tenochtitlan, whereby a number of Tencans received a concession to gather flies in the former's realm to feed the sacred quetzals in the great teocalli.—Maine Farmer.

The Calfalfa Mill at Kerman has just begun its regular winter run.

ARNOTT DOUBLE DISC HARROW

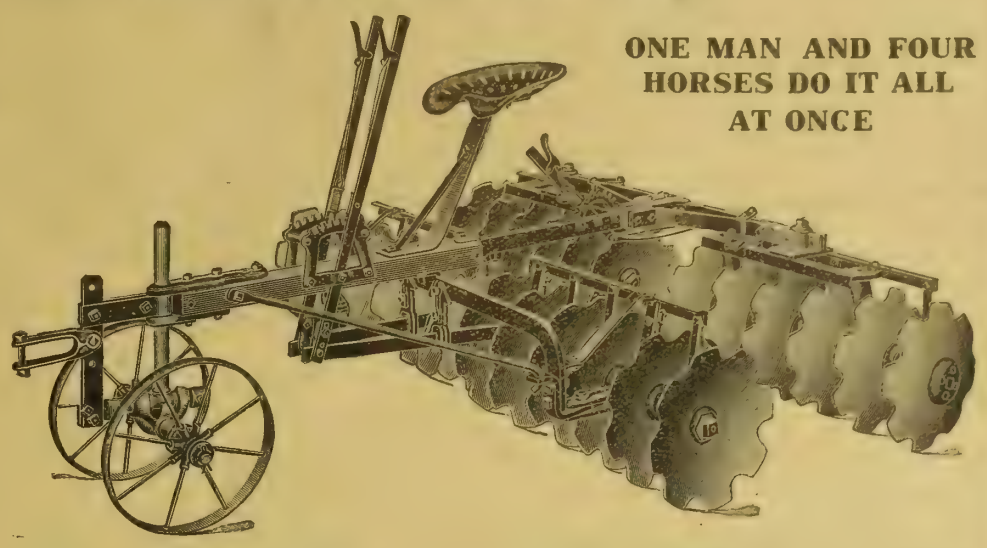
A Plow—A Disc—A Pulverizer—A Smoothing Harrow all in one

The SENSATION of the Day

Compare it Point for Point With Any Disc Harrow Made

Double Gangs
Double Cut
Double Throw
Double Levers

ONE MAN AND FOUR HORSES DO IT ALL AT ONCE



The flexibility of the **Arnott "Double-Cut"** in contrast with the stiff action of other two-way harrows is what is making it so popular. This flexibility is possible because of our Universal Joint connecting the front and rear gangs. For lack of this feature other double harrows have a good deal of side draft and will not make a square turn without digging a great hole. This can't happen on the **Arnott.** Independent front and rear levers within easy reach of rider.

Complete description mailed upon application. Write for prices

ARNOTT & COMPANY, Inc., Southwestern Gen. Agts.

112-118 South Los Angeles Street, LOS ANGELES.

All sizes in stock for immediate shipment, 4 to 10 ft. cut inclusive.

FARM LANDS FOR SALE.

For Sale—By owner, good farm land, $50 per acre, in Merced County, 9 miles from Merced and ½ mile from station on S. P. and 4 miles from La Grande on Santa Fe. This land is a rich, sediment soil, situated in the Artesian Belt and an abundance of water is thus assured. Is level and all under cultivation. No alkali, and is suitable for figs, corn, alfalfa, beans, and all farm crops. Will subdivide in lots from 40 to 1000 acres. This land is very cheap at the price. In fact, it is only one-half the price of other land in same locality. For further particulars call or address Paxton, 612 Lankershim Bldg., Los Angeles.

For Sale—A 20-acre farm for $20 cash and $20 a month; possession now; $90 to $125 per acre; your crops pay for the land. Rich, level land for alfalfa, oranges, almonds, grapes, cows, chickens; abundance of ditch water, for irrigation, for $1 an acre a year. Where else can you get this? In Oakdale Colony, near good town and railroad station, climate delightful. T. Wiesendanger, 207 S. Broadway, Los Angeles, Cal.

For Sale—Mountain home near Riverside. 160 acres hill land with concrete buildings in excellent repair, and 140 stands of bees in fine condition. Good spring close to house. Ideal location for healthseeker or chicken raiser. H. E. Wilder, R. F. D. 1, Riverside, Cal.

For Sale—815 acres in San Luis Obispo County. A typical dairy ranch. Plenty of wood, water, irrigable land, buildings, fenced and cross fenced. Orchards, vineyards, oranges, lemons and walnuts do exceedingly well here. Forty acres of land suitable for these. Price $21 per acre. For further particulars apply to Mrs. F. A. Clink, Pozo, Cal.

For Sale—The Fresno Meadows Colony is now opened for settlement in lots of 40 acres or more with water at $50 per acre. This is an opening price and is made to induce settlement. Arrangements can be made so that the first payment will carry the deal indefinitely. Call or write at once. Green & Webb, Gen. Sales Agents, 406 Laughlin Bldg., Los Angeles. Phone A8284.

San Joaquin Valley alfalfa land for sale with railroads, schools, electric power and cheap water at hand. 40-acre tracts and up at reasonable prices. Also several large stock and alfalfa ranches with artesian water. C. H. Biggin, Pixley, Tulare Co., Cal.

WICK'S WHITE FOWL FARM, Moorpark, Cal

THE PERCHERON SOCIETY OF AMERICA

Has just increased its capital stock to $100,000. 10,000 shares of $10 each. 3,000 shareholders, Nov. 28, 1910. 100 breeders have taken memberships since December 1st. Ninety-five per cent of the Percheron breeders of America record with the Percheron Society. Information pertaining Percherons furnished. Address Wayne Dinsmore, Secretary, Union Stock Yards, Chicago, Ill.

IN THE JANUARY CENTURY.

The important and valuable work being carried on by "an Iowa plant breeder," Mr. Charles G. Patten, of Chester City, Iowa, is the subject of a paper in the January Century, describing new methods in plant production as contrasted with old. It is by L. H. Bailey, director of the College of Agriculture, Cornell University, and the chairman of the Commission on Country Life in President Roosevelt's administration. It is Prof. Bailey's contention that the rational breeding of plants is to be a necessary part of the agriculture of the future, and that we are to look to this work for help in feeding and clothing the race.

General Household Notes

BY THE BEAUTIFUL BLUE DANUBE.

Calmly roll on, O Danube, roll!
Thy story is known from pole to pole.
In forest-clad hills rise silv-ry rills,
That grow as they go, and grandly flow
Past castle and town of high renown,
Where many a son hath glory won;
And great is the fame of the name
That thy bards have handed down.

Yet 'tis not the trill
Of the tinkling rill,
Nor the story
Of thy glory,
Makes our voices ring
When thy song we sing,
Tho' thy praises sound
Where hearts are found.

'Tis a strain we hear,
Mystic, quaint and clear,
Elf-enchanted,
Mem'ry-haunted,
In our heart-land where,
Like the childhood's air
Of a strong old song,
'Tis borne along.

My rippling waters call
To my children one and all;
Tho' in distant lands they roam,
On wings of the wind come songs of home.
And thro' the passing years,
With their joys, their hopes, their fears,
Shall my swell, my sweep, my sound
In the heart of their hearts' deep mem'ries be wound.

Treasure the days of thy youth,
Hear ye my waves complain,
Their waters once fled, of a truth,
Flow not back again;
But youth is rash and gay,
And will dash, and splash, and play
With the world, as tho' to say:
"I'll laugh, love and live for ever and a day."

In spring my flow halts a little at first,
The ice-bridge binds before it is burst;
Press warm, then, by night and by day,
It soon will melt away.
With melting glance must a maiden be pressed;
Woo warmly, then, and give her no rest;
Tho' oft-times her lips may say nay,
She will at last give way.

Walk with me, talk with me,
You like me, don't you dear?
Laugh with me, chaff with me,
You miss me, don't you, dear?
Sigh with me, cry with me,
You'll kiss me, won't you, dear?
Play with me, stay with me,
The live-long day!

The streamlets clear in the woods are so shy,
Say to me, "Why! marry, not I!"
Yet soon you'll see, they'll run gaily with me
Far, far away to the sea.
Ah, maiden dear, true and gentle thou art,
Yield him thy heart, till death you do part!
How long has he lov'd thee! Oh, answer him,
Say, he may love thee for aye!

Maidens, heed! Hark, the vespers ring!
Time is on the wing!
Beauty flies! Passion dies!
Seize the hour while now the whole world yet before you lies,
Lovers, plead! There their troth they plight,
All will now come right!
I must on, hurry on,
Other hearts there are that still are parted from their own.

Ding, dong, ding, dong!
Hear those bells!
They're wedding bells!
Hark! Hark!

Yes, I'll find some as I roll on my way
That are going to be married today;
And if some must wait for a year,
They will find me here.
For to your fathers and mothers sang I,
To your children I'll sing by and by;
When a thousand years shall be gone,
I'll be singing on.

Men must work
In their joy and woe,
And a maid must weep;
It is sad, it is so!
Laugh, love and live,
As I joyous flow,
Take what life can give,
And be cheerfully ready to go!
—Henry Grafton Chapman.

REFORMING A MAN.

"Any papers or messages you'd like to have taken to the office before you come down, Mr. Meadowcroft?" asked a pleasant voice through the telephone.

Meadowcroft hesitated. The voice belonged to his stenographer, who lived with her mother in a little flat a block from his home. She was a fine girl—came from the town where he had grown up. The relations between their two households were scarcely the usual ones of employer and employe. Perhaps it was on this account that he hesitated.

"Well, Miss Neltner," he said, "you know I have to go away out to the hospital to see Smith the first thing this morning, and I'm on the committee to meet those senators at the 11 o'clock train, and I don't know how I'm to get my silk hat ironed before that."

"Oh!" The voice was tentative now. Miss Neltner was wondering if he thought she could iron silk hats.

"I hate to ask you," he went on, "but do you suppose you could leave it at Dreer's—my tailor's—for me?" He'd fix it, and I could stop for it when I came down."

"Certainly," said Miss Neltner.

Twenty minutes later, Miss Neltner received the hat from the hands of her employer at the entrance of her own flat. Smilingly she closed the door behind him. Then she called, tragically: "Mother, look!"

A sympathetic face appeared in the doorway. "He's brought it in this big leather hatbox. And you ought to have seen his face! Its expression said: 'There! Any woman would be proud to carry a $12 hatbox like that!' What shall I do "

"Take the hat out and make a parcel of it."

"But it might get rumpled. Besides, he thinks he's brought me the grandest thing in the world to carry it in, and he's so kind I'd hate to have him know how I feel about it."

The end of it was that Miss Neltner boarded the car for downtown with a huge, misshapen, shawl-strap bundle hanging from her neatly-gloved hand. Her own steamer rug, folded around the hatbox, had solved the problem. It was bulky, but it had a feminine appearance at least.

"Hello! Where's the shawl strap going with you, Miss Neltner? I thought your vacation was done." The voice had never been unwelcome until that minute. Howard Thomas settled into a seat beside her, possessing himself of her luggage as a matter of course.

"I'm not going anywhere," she said hastily. But she saw no reason for explaining that her employer's hatbox was concealed inside that rug, so she changed the subject, and chattered all the way downtown, only losing her

Indispensable in Emergencies

THE sickness of a valuable animal on the farm demands prompt remedies.

It's a case for the veterinary—a case where minutes count. That's where the Bell Service shows its value to the farmer.

By means of the telephone the veterinary is reached, and he at once tells the farmer what to do until he arrives.

No far--sighted farmer gets along without the protection of the Bell Service.

He can never tell when it is going to save him from serious loss. Besides, he has daily proof of its usefulness:

spirits when the young man insisted on carrying the shawl strap to her destination. Conversation ceased entirely just before they reached the tailor's door, and when her companion yielded up the shawl strap there, she went into the building with the unhappy conviction that he thought her queer.

There was no time to nurse this conviction, however. Her explanation to the tailor kept her too busy.

"I understand!" Dreer laughed, as he shook the hatbox out of the steamer rug. "I'll have it ready when he calls. You're Mr. Meadowcroft's sister, aren't you?"

"Oh, no! I—I'm his stenographer," Miss Neltner stammered. Then she flushed because she had stammered—and immediately became scarlet with annoyance because she had flushed.

"Certainly. That's all right," Dreer assured her. But the more comforting he was, the less she liked it; so she got away as quickly as she could.

Arrived at her employer's office, she found an excellent chance to cry, but Miss Neltner is not that kind. Instead of wasting tears, she plans reforms. Meadowcroft, she reflected, was too good a man to go on making such mistakes. The thing to do was to teach him tactfully that there was a difference between proper masculine and feminine luggage.

Gradually a plan evolved itself. She would accomplish her end by an object lesson. Mrs. Meadowcroft was still in the country, where Meadowcroft went to pass Sunday with her every week. Miss Neltner had been knitting a voluminous pink wool wrap for Mrs. Meadowcroft. It was large and triangular, with long ribbon streamers. Instead of packing this in a box, she would thrust it, unwrapped, into Meadowcroft's arms, just as he was leaving for the country, and surely, before he got to his journey's end with that thing on his hands, it must occur to him that a man's hatbox might not be the most appropriate thing for a woman to carry, either.

Accordingly, just as he was boarding the train on Saturday night, she flashed into view. "Oh, Mr. Meadowcroft, I was afrad I'd be too late," she said. "Will you take this out to Mrs. Meadowcroft, with my love?"

"Oh, here," he cried, wildly rolling the thing together and throwing it back to her as he stepped on the moving train. "You'll have to wrap it up and let me take it out next week. Good-bye!"

"Kind-hearted little creature, it's too bad," he added to himself, seeing her look of disappointment. "But she must be crazy to expect a man to carry a thing like that around on his arm. Well, anyhow, she's learned a lesson."—Riverside Press.

"OH SAY" AND "OH SAID."

There once lived in Carson City, Nevada, a teamster known to the old community as "Oh Say." He was not a Chinaman, as one might think, but a German, and secured his name from ejaculating "Oh, Say," whenever he spoke to a person.

When the mines of the Comstock lode were opened, "Oh Say" drove a mule team from the shaft down to the crushing mill, and later on his mules were bought by the owners of the mine, and used for some years thereafter.

"Oh Say" got other mules, but always had deep regard for the first mules he ever owned, which went down into that mine to drag cars from the facing.

They were named "Oh Say" and "Oh Said," and for forty years they dragged ore on the lower level of Comstock mine, never coming to the surface, nor issuing in the open air.

But every holiday "Oh Say," the man, went through the Sutro tunnel to visit his old mules in the bowels of the earth.

He carried them carrots and other delicacies for a mule's palate, and returned with curious stories of their affectionate recognition.

In the long interval the teamster had become a freighter, and from that had drifted into the most important business of the state. Only his intimate friends recalled him as "Oh Say," but others spoke of his as the "Hon. William Keyser," and Mr. Keyser never forgot his mules down on the last level of the Comstock mine, where they dragged ore through the long, dripping culvert called "Sutro tunnel." The managers of Comstock mine finally introduced machinery to haul out to the dumps, and the twenty or thirty mules were out of the job.

The Hon. Wm. Keyser promptly bought his mules, "Oh Say" and "Oh Said," and brought them to the surface of the earth, where they met the sunlight for the first time in nearly half a century. He turned them into the rich pasturage which formed the lawn about his fine home in Carson City.

There they lived in clover the short period of two weeks, and there they were both found dead one morning, cradled in alfalfa, which had once been a great joy to them, but from eating too much had caused their death.

The Hon. William Keyser buried them where they died, and reared over their tomb a carved stone which bears this inscription:

"OH SAY" AND "OH SAID"

Two Mules Who Contributed More to the Prosperity of Nevada Than the Silver King

They worked in the Comstock for forty years. They never took a dollar out of the state, but they moved millions of the values of its treasures. This stone is raised by their old friend, who seeks no higher reward than to rest beside them.—Dumb Animals.

RABBIT RECIPES.

Barbecued Rabbit.

Wash a nice young rabbit carefully; lay it in salt water half an hour. Place it in a broiler, cook quickly, basting with butter two or three times to keep from getting dry. When tender and nicely browned, place it in a pan, season with butter, pepper and salt; set it in the oven, let it remain for ten minutes, turning it constantly that it may soak up the dressing. Heat thoroughly two tablespoonsful of vinegar or tomato catsup and one teaspoonful of made mustard; pour it over the rabbit, baste well, let it stand a moment. Serve hot. (An old Southern recipe.)

Creole Rabbit.

Cleanse well and joint a young rabbit. Dip in melted butter, then in crumbs, and fry brown in one tablespoonful of butter and lard mixed (bacon fryings if at hand). Add two sliced onions and fry all together; add a cupful of tomatoes, sprig of parsley, thyme and bay leaf finely minced; cover and let simmer over a slow fire, stirring occasionally, until nicely browned. Add a cupful of soup stock, if you have it; if not, a cupful of water; season with a teaspoonful of salt and one-fourth saltspoonful of

Figure on Painting This Spring

A second short flax crop keeps linseed oil up, but the increase in price in pure white lead paint is not so great as you may fear.

Get at your dealer's the cost of 100 pounds of "*Dutch Boy Painter*" White Lead, 4 gals. pure linseed oil, 1 gal. turpentine, 1 pint turpentine drier—this makes 8 gallons of old-fashioned paint.

Compare this cost, either by the gallon or by the job, with what you used to pay for paint.

You'll find the difference so small that you can't afford to put off painting, or to paint with anything except "Dutch Boy Painter" White Lead. Write for free "Painting Helps No. 126

paprika. Cover closely and let simmer one hour.

Baked Rabbit.

Use two rabbits, and place back up in a baking pan. Arrange around them five medium-sized sweet potatoes (peeled). Allow one cupful of crushed, roasted peanuts to three cupfuls of dried bread crumbs. Mix with the crumbs two tablespoonfuls of butter, then add the nuts. Pile this mixture in one end of the baking pan. Chop three onions. To these add one-half a cup of butter, four teaspoonfuls of chili sauce and two of salt. Mix thoroughly and spread evenly over the rabbits, potato and dressing. Pour into the pan one cupful of sweet milk, and with this baste the contents of the pan every ten minutes, adding more milk as the baking causes the first to evaporate. Allow from one to one and a half hours for baking.

Rabbit en Casserole.

Wash and cut into pieces two young rabbits. Soak in salted water an hour to sweeten them, and to remove any clots of blood that may be found where the rabbits have been shot. Cut two small onions in slices, also two small carrots and two or three stalks of celery. Saute in a tablespoonful of bacon fat until browned, and add a cupful and a half boiling water or stock, pour over the rabbit in the casserole, cover and place in the oven to cook. When half done, sprinkle with a teaspoonful and a half of salt, two shakes of paprika. Make a sauce from juices in pan and serve in a sauce boat.—Rural New Yorker.

HOMELY HINTS.

Molasses will remove grass stains. Dip ink spots in hot tallow, let the cloth cool, then wash.

Remove coffee stains with a mixture of yolk of egg and luke warm water; use as you would soap.

A sewing teacher gave the length of the thread (to make time) from the finger tip to elbow.

When cleaning fish, use a pair of old scissors for cutting off fins, tail and slitting; save time and your nerves.

Add a little borax to starch, a teaspoonful to three quarts of starch; makes the clothes stiffer and more glossy.

If baby's cap is dried on an inverted bowl it is not necessary to iron.

Camphor will remove fruit stains from most garments without taking out color.

If you stumble over a stone use it for a stepping stone next time you pass that way.—Uncle By.

A man who loses wealth loses much.
A man who loses a friend loses more.
A man who loses courage loses all.

Recipe for securing love: Give love.—Tulsa Post.

CONTENTMENT.

Let us learn to be content with what we have; let us get rid of our false estimates, set up all the higher ideals—a quiet home; vines of our own planting; a few books full of the inspiration of a genius; a few friends worthy of being loved and able to love us in return; a hundred innocent pleasures that bring no pain or remorse; a devotion to the right that will never swerve; a simple religion empty of all bigotry, full of trust and hope and love—and to such a philosophy this world will give up all the empty joy it has.—David Swing.

BE OF GOOD CHEER.

Be of good cheer, brave spirit; steadfastly serve that low whisper thou hast heard; for know, God hath a select family of sons now scattered wide through earth, and each alone, who are thy spiritual kindred, and each one by constant service to that inward law, is weaving the sublime proportions of a true monarch's soul. Beauty and strength, the riches of a spotless memory, the eloquence of truth, the wisdom got by searching of a clear and loving eye that seeth as God seeth. These are their gifts, and Time, who keeps God's word, brings on the day to seal the marriage of these minds with thine, thine everlasting lovers. Ye shall be the salt of all the elments, world of the world.—Ralph Waldo Emerson.

THE TOUR OF A SMILE.

My papa smiled this morning when
He came downstairs, you see
At mamma; and when he smiled then
She turned and smiled at me;
And when she smiled at me I went
And smiled at Mary Ann
Out in the kitchen, and she lent
It to the hired man.

So then he smiled at some one who
He saw when going by,
Who also smiled and ere he knew
Had twinkles in his eye;
So he went to his office then
And smiled right at his clerk,
Who put some more ink on his pen
And smiled back from his work.

So when the clerk went home he smiled
Right at his wife, and she
Smiled over at their little child
As happy as could be,
And then their little child, she took
The smile to school, and when
She smiled at teacher from her book
Teacher smiled back again.

And when the teacher passed on one
To little James McBride,
Who couldn't get his lessons done,
No matter how he tried;
And Jamesy took it home and told
How teacher smiled at him
When he was tired, and didn't scold.
But said: "Don't worry, Jim!"

And when I happened to be there
That very night to play
His mother had a smile to spare
Which came across my way;
And then I took it after while
Back home, and mamma said:
"Here is that very selfsame smile
Come back with us to bed!"
—Woman's Home Companion.

BE FRIENDLY ON THE WAY.

I have journeyed on life's highway till the dial points to noon,
And I've learned some useful lessons on the way;
I have proved them o'er and o'er, and I prize them more and more,
And I think you can depend on what I say.
You may hold yourself aloof, and may think it is a proof
That you're made of some superior sort of clay;
But you'll always find it pays in many different ways
To be friendly to the people on the way.
—Wisconsin Farm.

THE HARVEST.

What hast thou for thy scattered seed,
O Sower of the plain?
Where are the many gathered sheaves
Thy hope should bring again?
The only record of my work
Lies in the buried grain.

What is the harvest of thy saints,
O God! who dost abide?
Where grow the garlands of thy chiefs
In blood and sorrow dyed?
What have thy servants for their pains?
This only—to have tried.
—Julia Ward Howe.

STAR PORTABLE DRILLING MACHINES

More Profitable Wells

Can be drilled with the right machine. In buying a Drilling Machine, the first vital point is to be sure it will yield you the greatest possible service—and hence the greatest possible profits. You *must* know.

Scott, Magner & Miller say:

Arrivals of hay on the San Francisco market for the week ending today have amounted to 2850 tons.

We are much gratified at the splendid lot of rain that we have had throughout the entire week. It has relieved the tension completely, and reestablished confidence in the business situation throughout the entire state. The feeling of uneasiness that was felt by farmers, merchants and all the business interests on account of the lack of rains has been thoroughly quieted by this storm, and as soon as it is over, work will again proceed satisfactorily throughout our entire sections. This has been a wonderfully satisfactory cause for gratification to everybody concerned, and a benefit to every industry in our state.

The demand for hay for shiping purposes has been a trifle better recently, and while no large orders have been placed from along the coast, yet the aggregate of the hay leaving this port has been a little better than usual.

Alfalfa hay has been looking up a trifle, for the reason that there has been some purchasing made in the interior which has caused a little ripple in the market, although the demand in San Francisco and in Oakland for alfalfa hay of late has been rather quiet.

We quote the wholesale prices in round lots on today's market as follows, viz.:

Fancy wheat	13.50@14.00
No. 1 wheat or wh and oat	11.50@13.50
No. 2 wheat or wh and oat	10.00@11.00
Choice tame oat	12.00@12.50
Other tame oat	9.00@11.00
Wild oat	8.00@10.50
Stock hay	6.00@7.00
Alfalfa, ton	9.00@12.00
Straw	40@50

Grain.

Wheat, No. 1	1.47½@1.55
Barley, fancy	117½@1.18¾
Barley, good to choice	1.13¾@1.16¼
Barley, poor to fair	1.10@1.12½
Oats, white	1.45@1.55

Rye, new crop	1.50@1.60
Alfalfa seed	18@20
Mustard, brown	2½
Millet	2¾
Flaxseed	5@5½
Broom corn seed, ton	23.50

Feed Stuff.

Bran, ton	29.00@30.00
Feed cornmeal, ton	34.00@35.00
Cracked corn	34.00@35.00
Ground barley, ton	23.00@24.00
Rolled oats, ton	29.00@31.00
Middlings	34.00@36.50
Oil cake, ton	40.00@41.50
Cocoanut cake, ton	24.50@25.50
Mixed feed, ton	25.00@27.00
Shorts	29.00@31.00

Citrus Fruit Market

LOS ANGELES, Jan. 18, 1911.

An unfortunate defect is developing in many shipments of oranges in the specking or spotting of the skin. This does not affect the real quality of the fruit, but does affect its appearance so that selling at the most satisfactory prices is prevented. It is far less disastrous than actual decay, and it is hoped the matter will be overcome in a short time. The auction reports given below average much lower than other markets, because much of this unsatisfactory fruit has been passed on and disposed of there.

Lemons are being better received than formerly, from 25 cents to 35 cents above last week's quotations being commanded at this time. The fruit is excellent, and much of that which is being cut at this time is being stored for later delivery.

Shipments.

Shipments of oranges from November 1, 1910: 4970 cars, lemons 843 cars, total of citrus fruits 5813 cars. To same date last season, oranges 2515 cars, lemons 793 cars, total 3308.

NEW YORK, Friday, Jan. 13.—Nine cars navels, one car lemons sold. Unchanged oranges and lemons. Raining.

NAVELS—	Avge.
Independent, Growers F Co	2.30

ANNUAL POULTRY NUMBER

The Big Weekly { Fifty-two issues, each containing from 24 to 32 pages of practical information, } For $1 the Year

California Cultivator

An Illustrated Weekly devoted to Horticulture and Agriculture

LOS ANGELES JANUARY 26, 1911 SAN FRANCISCO

SUBSTANTIAL CALIFORNIA POULTRY HOUSES AND YARDS

On this page is presented a group of views picturing what in the writer's mind is indeed a substantial and practical poultry house, and improvements calculated to contribute largely to the comforts and contentedness of fowls, and the stimulating of egg-production on the part of the hens. Some may say that this claim is a trifle extravagant, nevertheless this opinion is based on wide observation and years of experience both East and West. Properly constructed and intelligently managed this style of house and yard will "pull down" as much hen fruit in winter from a given number of hens in any climate as any other style with which we are familiar. It is widely known as the roosting room and scratching shed house, and it is so modeled that much time, expense and lumber is saved in building; it can be continued to any desired length in one line. A feature is its scratching-shed. This shed is ten feet square, where the birds work for their fine grain ration. There is no prettier sight than one or two dozen hens singing, hustling and scratching in about ten inches of clean wheat or oat straw, where their evening meal has been scattered. It is advisable to keep a fowl busy, contented, and in good laying condition in this work shop.

The house proper, which is shown in the cut, illustrates the sleeping quarters. This is not alone for roosting purposes, but also contains the laying nests. Perches are just sufficiently high to avoid the cold air and the effluvia from the floor and droppings. Under perches is a wide pan built to slide in on cleats to catch the droppings; immediately beneath this pan are the nests.

Talk about results. This house back East where the mercury often drops to 16 degrees below zero, produced for the writer 19 to 25 eggs every day during the winter out of 30 hens. Cut also gives partial views of yards, which are eighteen feet wide, and made any length desired.

The two views at the top show houses originally constructed as rabbitries—now only a memory of the crazy Belgian hare boom that had us all going several years ago. In spite of that sporadic and flamboyant event, the Belgian hare is not without its economic value. For the service of man in the practice of our modern domestic economy there is nothing to quite take the place of a well-grown, nicely fatted young Belgian hare. As a means of fighting the meat trust, this little quadruped certainly has virtues worthy of our consideration.

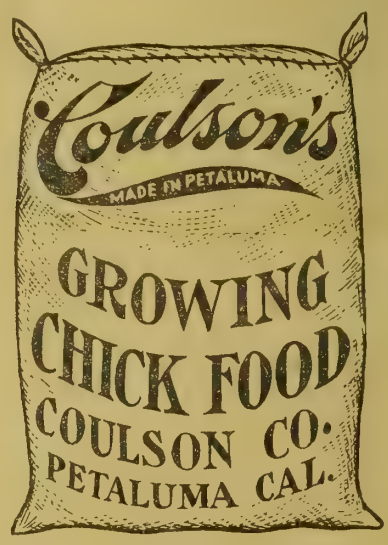
POULTRY RAISING MADE EASY

Scientific Poultry Raising means scientific feeding—feeding which will supply the greatest amount of egg producing energy, give the bird a strong constitution and render her least liable to disease. When you fail to furnish the most beneficial elements you are simply trying to run an egg factory without the proper material.

We are Manufacturers of Poultry Food for Birds Of Every Age

For the little chick which has recently broken its shell to get out into the world we make Coulson's Special Chick Food. This food is carefully selected to meet the demands of an intricate and delicate body. The parts composing it are all thoroughly cleaned, well granulated and carefully mixed to give the right proportions. Use this food for six weeks, when your chicks will be ready for

Coulson's Growing Chick Food



This food is a little stronger than the Special Chick Food, contains additional properties, which the chick is now able to digest, and is a great body builder. It produces muscle, bone and sinew, gives correct bearing to the chick and carries it safely on to the period of eggs and market.

Coulson's Egg Food

When the pullets are three to four months old give them Coulson's Egg Food, which will bring them in good health to the laying time, and start them right. The surplus strength of the food now goes into the making of eggs, and the exhaustion occasioned by producing them is therefore readily compensated for in the Egg Food, as it furnishes the needed ingredients.

In conjunction with Coulson's Egg Food, Coulson's Scratching Food fed once a day gives a variety in grains and seed which is very beneficial.

You can buy our goods from any reliable poultry dealer. They are on sale everywhere. If your dealer cannot supply you write us and we will tell you where you can get what you want. Send to us for our free book, "Poultry Feeding for Profit," and for any information on poultry matters and we will forward it.

Vol. XXXVI. No. 4. LOS ANGELES: THURSDAY, JANUARY 26, 1911 One Dollar the Year

The Great American Business Hen in California

Development of Hen Farming.—Feeding and Caretaking.—Insect Foes and Disease.—Preventives and Remedies.—Marketing a Crop of Newly Laid Eggs.

Henry W. Kruckeberg

Poultry culture has its place in our agricultural development. And though only a "chicken business," by reason of the units of which it is made up, in the aggregate it outstrips in money value many of our staple orchard and field crops. Statistics give it an annual importance of about seven hundred millions of dollars in the United States. By reason of its wide distribution into small units of production it suggests the busy bee gathering tiny bits of nectar from countless thousands of blossoms which go to make up the carloads of California honey that are annually exported. In California, the American hen has gained a strong foothold, and is daily growing in importance. We can boast of possessing in Petaluma the greatest poultry center in the country,—and yet, California annually imports many dollars worth of poultry products. Between these two statements there is a field for exploitation and a world for improvement. There is no reason why California should not supply her own markets. Poultry is exported from Northern California at certain seasons of the year, but only during the winter when biddy is more or less out of business in the colder regions. Why is this? The reasons are many and diverse, but they are insignificant compared to the fact that poultry culture has with us never attained first-class importance in the sense that fruit growing has. Our best endeavor has been plant culture rather than live stock. But we are growing, and the industrious hen is gradually coming into possession of her own.

WH. LEGHORN. MEDITERRANEAN.

With most people the matter of breed and variety is already settled. It is after all in its last analysis a matter of individual taste and purpose. All breeds are good in the hands of good breeders. Generally speaking, however, the Mediterranean class seems to have first call in California, with the American and English as close seconds. The feather-legged sorts are not popular. And while we may feel satisfied as to our breed and variety, no one will feel quite right unless his birds are up to Standard requirements. By "standard" is here meant fowl answering to the requirements of the American Poultry Association's "Standard of Perfection," a book that occupies the same relation to poultry that similar books do to cattle, horses, hogs, etc. And do not imagine that the book's requirements serve only the ends of beauty—far from it, for it has been quite well established that the standard bird is also the paying bird. The scrub as a whole is an undesirable quantity devoid of economic quality as well as points of beauty. Since breed and variety is a matter of taste, we may go on a step further.

SIL. PEN. WYANDOTTE. AMERICAN.

Artificial hatching and brooding is, of course, germane to our subject, but in this paper it will be avoided (1) because the average farmer and fruit grower still adheres to nature's way of replenishing his flocks, and (2) because many now resort to the purchase of the day-old chicks direct from the professional hatcheries. This practice is destined to be extended until we shall be able to buy three-months old pullets in much the same way. The nucleus of such a business is already in evidence at Petaluma. Mating is another item worthy of a paper of its own, but for our present purpose it will suffice to state that you would mate your most vigorous males, the ones that evince pugnacity, are great feeders, rapid growers, active, alert and "boss of the roost," to your best laying females characterized by a corresponding vigor, health and good, motherly qualities. The progeny of such is apt to partake of the best qualities of both parents.

The clutch of eggs is off or the brood of peeping young are in from the incubator to the brooder. For the first 24 hours they should be left alone, after that they will require constant attention if we are to obtain good results, whether we aim at a supply of hen fruit or carcass for market. The usual practice is to hard-boil an egg, chop it fine, shell and all, and then mix it with an equal amount of bread crumbs or cornmeal or oatmeal; this is the first meal. This food should be kept up for two or three days,—after which we feed with ground wheat, corn, shell and bone, also green food, such as cut alfalfa, lettuce, etc. The standard chick foods now on the market are being widely used, and invariably give satisfaction. It is a good practice to feed often, but little at a time, say every two hours, or four and five times a day until the chicks are five or six weeks old. Always be sure that no food remains in the vessels or runs after they have eaten, to become sour. Nothing is so prolific of bowel trouble and dysentery. In my own case, with some forty fowl bred "on the side," the egg and bread diet is continued for three or four days, when it is at once substituted for the morning mash fed to the adult poultry. This mash for the most part contains the waste from the table accumulated the previous day. A large iron kettle stands on the back of the kitchen range, into which are placed the available leavings—bits of meat, vegetable parings, cast-off bread, etc. The morning following this is all cooked by the addition of the proper amount of water, when sufficient bran is added to make a mash. Into this is also added a pinch of salt and a scant teacupful of bone and blood meal. Give only what the fowl will eat up clean in about 20 to 30 minutes. We feed in galvanized iron troughs. At midday we give liberally of green food—cut alfalfa, lettuce, Swiss chard, cabbage, chopped onions, beets, or whatever is most convenient, all the time aiming to have as great a variety as possible. At night grain, principally cracked corn and wheat, which is supplemented with millet, hemp, canary and other seeds, as occasion suggests. It is quite apt to be a mooted question with beginners just how soon to commence feeding grain food to young chicks. The chick cannot be too soon supplied with food that will require the grinding of the gizzard to be properly brought into action. Soft food will not do this, consequently, more or less dry food must be supplied. In the gizzard, with the aid of some grit, the woody envelope of more nutritious parts of seeds and grain is ground into atoms, also the nutritious parts thus prepared for digestion and assimilation. Some gritty substance is absolutely essential; for without it the gizzard cannot properly perform its work. Even baby chicks should be fed upon a sanded floor. The gritty matter should be as hard and sharp as possible, so that it will grind up the bones and such like substances. When chicks are young, broken wheat, coarse oatmeal, canary seed and some hemp seed are each very suitable. They should not not have much, if any, Indian corn, as it makes them too fat, and thus renders them liable to a variety of ailments. For stock purposes a fat fowl is undesirable, for its progeny is almost certain to be weak. The question is often asked, "How shall we feed a flock of hens?" That depends somewhat on our purpose. If for eggs, we must largely provide those elements of which the egg is formed; if for table purposes the ration should be rich in the fat and meat building constituents. Fifteen per cent of animal food, twenty-five per cent vegetable, and sixty per cent grain; the

OLD TRUSTY

Let me send you my big, new, 1911 Old Trusty book and confidential personal letter right away. Tells you how much less than $10 I charge you this year for one of my world-famous Old Trusty Incubators—freight prepaid east of the Rockies. You see, I'm working on 100,000 machines this year on a makers profit of only 7% or less, so I can put the price way down even though I always keep up my highest standard in workmanship, materials, and guarantee 80% hatches or better. And my 10-year High-Quality Guarantee is Johnson's—backed by all Johnson's property, cash, factories and a lifetime reputation for square deal on Old Trustys. When I made only 50,000 Old Trustys I had to charge 16% profit, but chicken raisers, both beginners and experts, have bought so many Incubators from me that they forced my factory capacity up to 100,000 and I'm giving it back to my customers by keeping only 7% or less, profit now on each machine. Old Trusty is better and surer than ever this year. Handsomely metal encased and asbestos lined. Hundreds of thousands in successful use now—3 times as many as any other made.

more varied this grain food the better, while the vegetable substance with us is preferably alfalfa. Beans, ground, when they can be bought at the corresponding price with other grains are excellent, for they contain thirty-eight per cent muscle forming material as compared to seventeen per cent in barley, twenty-two per cent in oats, and eleven per cent in corn—the corn having the greatest quantity of fat or heat; but the beans had best be part of a composite meal made about in the following proportions: 15 pounds corn, 15 pounds beans, 10 pounds barley, 15 pounds oats and 15 pounds wheat bran. Of this grain should be 60 per cent of the ration, with 15 per cent animal and 25 per cent alfalfa or other vegetables, the mash thoroughly scalded.

As to quantity, feed only what they will eat up clean in 20 minutes on a clean run. After this quantity is ascertained, if grain is fed, rake it into the runs or else supply litter into which it can be thrown. Some means must be provided to keep confined poultry constantly at work. Exercise is of as much importance as intelligent feeding. Dry feeding in hoppers to which the birds have free access at all times was a lively topic of discussion a few years ago, and found many followers, and was quite generally adopted. The theory was that it would be more economical, and save the labor of preparing the mash food, and give the birds all a fair show at the pie counter. Of late years it has been less in favor. The fundamental methods of feeding are grain, grain and dry mashes, and grain and the wet mashes, each, of course, supplemented with the green food. Breeders in their opinions and practices vary more or less as to which method is best; good results being possible by all three. Balanced rations also vary, being governed by the available materials and market prices. In California there is a decided tendency toward the practice of buying poultry foods already prepared direct from the manufacturers and dealers, as we shall notice a little later on. Where fowls are confined green food must be supplied, and nothing is superior to cut alfalfa. Another item please remember, and that is a plentiful supply of pure water furnished in clean and pure vessels or drinking fountains. Birds in a state of nature have access to plenty of gravel or coarse sand with which to grind their food. See to it that under artificial conditions there is an abundant supply of ground shell, fine gravel, coarse sand, broken crockery or glass pounded into particles the size of peas. And please do not forget that cleanliness is the badge of civilization, and to the contrary, that filth is degenerating, and no business ever yet was successful in squalor and wretchedness—least of all the business hen. As supplemental to cleanliness do not forget the dust bath, it is nature's bath tub for the hen, and is a preventive of lice and filth.

In the interests of economy and better results in product, as just noted, many commercial breeders are buying their feeding stuff in the prepared state—this gives more time to intelligent caretaking of the birds and enables a closer study of their requirements. Poultry and chick feeds now constitute a business by themselves, and right here at home we have a number of establishments that turn out many carloads every year. But the division and specializing of the business goes even further. Experience has taught breeders that it is better to center on one branch of the business. As a result of this we note the egg-farmers, the professional hatcheries, the manufacture of feeds, the growing of three-months-old pullets on contract, which finds its chief exploitation in Petaluma, and other innovations, all tending to a singleness of purpose, in which the specialist excels and so reaps a corresponding return. If, as Dr. Johnson said, "Bad dinners go hand in hand with total depravity, while a properly fed man is already half saved," the importance of good living for poultry is apparent; it of itself is almost proof against disease.

In California poultry should find ideal conditions—and so it would, did not its insect foes also find congenial environment. The bugs affecting web and feather are not only numerically strong, but persistent and pugnacious. The mites, the head and body lice are indeed the bane of the breeder and the torment of his fowls. It seems almost impossible to breed poultry literally free from parasites. Like the poor, they are always with us. Young chicks should have their heads greased for the destructive head louse three or four times. First, the day following their birth; again when a week old; and a third time at the expiration of about 20 days. If the bird appears droopy after that period repeat the operation, using only enough grease—sweet oil, butter or lard—to thinly coat the head. Use insect powders freely in nests and thoroughly dust it into the plumage of infected fowls. Use whitewash liberally inside and outside of the houses, applying with a spray pump, and be particular to swab all roosts with liquid lice killer at least once a month.

Disease? The best way is to have none of it in your flocks. Proper feeding, pure water, good houses and cleanliness are a quartet that when properly applied will do much to avoid sickness in your poultry. A sick fowl patient is indeed a bad actor, and should be hissed off the poultry stage. To even touch on the subject of diseases and remedial measures is hazardous and tedious. For ourselves sick chickens not only give us that tired feeling that you read about, but an acute pain in the head. Bowel complaint, roup, swell head and indeed most of the ills that chicken flesh is heir to, are invariably traceable to bad housing, improper feeding, and filth. As with persons, change of diet, of environment, of conditions, will often bring biddy back to sprightliness and vigor. There are many so-called remedies for chicken ailments, but a sick fowl means a sick profit, and the good Lord knows we have enough of that already. At best, if seemingly cured, the recovered specimen is still a menace to the flock, as its progeny is bound to inherit traces of weakness and be wanting in vigor and pugnacity. Hence, let me admonish the beginner to eschew by every means the presence of disease, or weak, under grown and undeveloped specimens. In spite of these negative reflections we will venture a few suggestions calculated to bring about normally healthy conditions, or at least act as deterents to the advance of Generals Bacteria and Microbe and their ragged and emaciated army of ailing soldiers.

Keep clean. This means sanitary houses, sanitary yards, and sanitary appliances. To keep the premises pure and sweet sprinkle powdered air slaked lime in runs and houses.

Be sure of your food and water being clean and wholesome. Water and food-borne diseases are not uncommon in the poultry yard. The former can often be purified of infectious elements by the addition of permanganate of potash.

Wholesome food. Moldy bread, musty grain, decaying vegetable matter, tainted meat, are unfit for hens, because leading to inflammation of the intestines which finds expression in diaorrhoea.

Charcoal prevents disease by its absorptive powers of the gases in the system; and also for its physical

action. If available, poultry will eat of it quite freely.

Common hard soap dissolved in water to the consistency of soft soap, one tablespoon to the gallon of water will often clean out nostrils and throat, and act as a mild purgative.

Onions fed liberally with red pepper chopped fine in the mash has a tendency to fortify the system against colds. The former if fed for any length of time, however, has a tendency to influence negatively the flavor of the egg.

Epsom salts is a simple drug calculated to maintain the system in robust condition. Give about a teaspoon to each twelve hens once a week. To afford all birds a chance at the medicine bottle, dissolve the salts in just enough water to take them up. Then employ this liquid in mixing the mash, making it dry and working it over and over. Give this for half a feed. In this way the birds all get a share. Salts cool the blood, clean the intestines and stimulate the action of the liver and other excretory organs. With Epsom salts and peroxide of hydrogen, which is a cleaning agent and a destroyer of disease germs, for external use, in case of sores, wounds, etc., one has two simple things with which to combat physical ills. To these add a box of quinine capsules of one grain size to be used with colds or droopiness, as it stimulates heart action. A box of liver pills might also be added.

But a religious regard for cleanliness and good sanitation, beats all remedies. Learn to remove the cause of disease and you will have only healthy and contented birds.

There are some who think it toughens fowls to allow them to roost in trees in the open; but I notice they are not among the most successful breeders. In this climate a warm house, in the sense that the term is applied in the East, is not necessary. Constructed cheaply and of light material it should be draught proof, with but a single opening for ventilation.

In the matter of contracting, harvesting, packing and shipping your crop of hen fruit, let me suggest:

1. Use hens that produce not only goodly numbers of eggs, but those of standard size: Leghorns, Rocks, Orpingtons, etc.
2. Good housing, regular feeding, clean, dry nests.
3. Gather your crop of hen fruit daily; when the weather is 80 degrees and over, twice.
4. Confine broody hens as soon as they show symptoms.
5. Reject all doubtful eggs found in a nest that has been missed.
6. Place summer eggs in a cool place as soon as gathered.
7. Avoid moisture coming in contact.
8. Dispose of young cockerels or segregate from the hens. Do the same with the cocks, out of the breeding season.
9. Sell your cracked and dirty eggs to your household.
10. Market not less than once a week, and as much oftener as practicable.
11. Keep all hen fruit as cool and dry as possible while in transit to market.
12. Keep eggs away from strong odors and out of musty rooms and cellars.
13. Use strong and clean cases and perfect fillers.

Success in poultry culture, whether on a large or small scale, is after all a matter of individual effort and persistent application. Faithfulness, a punctual observation to every detail, coupled with a love for the birds are essential to its successful prosecution. In so far as mere words go, the price of success may be summed up as follows:

1. Stock answering to standard requirements.
2. Cleanliness in every department.
3. Fresh air.
4. Abundance of pure water.
5. Proper feeding, coupled with grit.
6. Sanitary houses and yards.
7. Intelligent caretaking.

These basic principles should be well mixed with brain and brawn. Administer freely. If properly and persistently applied success will follow. One hundred doses for the asking at the Energy shop of Elbowgrease & Commonsense. Money back if unsatisfactory.

This open front door makes perfect ventilation

Mandy Lee is Miles Ahead

It is the only Incubator without a "Sealed," Air-tight Egg Chamber. It supplies the life-giving oxygen freely, draws off the carbonic acid gas, and is saving the lives of millions of chicks.

READ the story of the Mandy Lee triumph in our new catalog. Other incubators are already preparing to imitate and profit by our great discovery.

No guessing with a Mandy Lee

You cannot afford to buy an old-theory incubator which may go out of date and be discarded next year. You should know the truth *now* about the great discovery. The book is free. Ask for it.

There IS Something New in Incubators

We have taken the boldest and most important step ever taken in incubator building. See the openings into the egg chamber? They mean the saving of chicks' lives. It is the key to *right* hatching. Ventilation in the Mandy Lee is now perfect. It goes on all the time, neither above nor below, but right *at the eggs.* Every minute of the hatch the life-giving oxygen is freely passing in to the eggs and the carbonic-acid gas is passing out. And correct ventilation is just one of the great Mandy Lee features.

We Don't Guess—We Measure

The Mandy Lee is as far in advance of other incubators in heat and moisture as it is in ventilation. We do not guess at anything. The sensitive regulator controls heat to the fraction of a degree and *we measure moisture* just as accurately with the Mandy Lee Hygrometer (one sent with every incubator). You know what you are doing. *You* measure and control moisture; *you* control the hatch. The Mandy Lee is the all-season, all climate, all condition hatcher, always producing the most and the strongest chicks.

NEW OUTDOOR BROODER
Heated—Storm-proof

Mandy Lee Brooders give direct contact heat to the backs of the chicks. That is *real* mothering, the most important thing in poultry. Hovers are raised and lowered as weather gets warmer or cooler—heated from end to end. Chicks do not pile up and smother. Write to-day for catalog and full information.

Cycle Hatcher Company, Oakland, Cal.

Gentlemen:—A year ago we started with the Philo System and raised as fine a lot of White Orpington pullets as anyone would wish to see. They have started laying and we certainly are proud of them.

The two machines we purchased of you last season have given excellent satisfaction. We shall probably need more this year and shall use Cycle machines in preference to a larger incubator.

Yours truly,
S. N. HAINES.

"Chicks Well Hatched are Half Raised"

San Jose Hatchery, San Jose, Cal.

Day-Old Chicks

One of our Incubators (2000 egg capacity) just after hatch.

We are particular about the vigor and vitality of breeding stock from which we use eggs for hatching. This is the first essential to secure strong, healthy chicks. We use the best incubators we could procure. The eggs are given required care and attention while hatching so that you are assured to get good, strong chicks. Greatest care used in packing and shipping, that chicks reach you in good condition.

Prices per Hundred Chicks

Brooding and First Care of Chicks

F. E. BALDWIN.

The proper brooding of chicks is, in our opinion, the most important part of the poultry business. It is a well-known fact that just prior to hatching the chick draws up into its body the remainder of the yolk, and in this way starts on its journey with a three-days ration in its haversack.

What the chick most needs during the first three days is to be kept warm; true, it must have air, but heat is absolutely necessary for best results in growth and development later on.

These facts lead to the conclusion that it is better to keep the chicks in the incubator for a day or two after the hatch is over, for the reason that heat conditions can be regulated more perfectly and easily. Of course, if the hatch is large it will be necessary to remove a portion of those first hatched, which are crowding against the glass doors. The later ones may then have more room and air. It is well to keep the incubator doors darkened, so the chicks will not crowd to the front, but spread out—"go 'way back and sit down," as it were.

We remove the trays after the hatch is well cleaned up, so as to give the chicks all the room possible, and keep the temperature, as shown by the thermometer, the same as during the period of incubation. Of course, the chicks are now about four inches below where they were when on the trays, and the temperature is much lower. They are, however, close enough together, though somewhat spread out, to help each other keep warm.

Before transferring the chicks to the brooders we heat the nursery end to a temperature of 95 to 100 degrees with the bulb of the thermometer under the hover, four inches from the floor. We put in the brooder a font of water, the drinking rim of which is one and one-quarter inches above the bottom. This font we place on a square board one inch in thickness, which projects an inch or two beyond the bottom of the round galvanized iron font. This arrangement prevents the litter being scratched into the drinking water, and yet the baby chicks will find the water by stumbling up onto the board. These fonts of water should be placed in the brooders so they will be warmed up some before the chicks take their first drink.

We also place fine grit on one-half inch boards with a rim around the edge to keep the grit from getting off of the boards. These boards can be turned over, as the rim about the edge is made by nailing a three-quarter-inch half-round moulding to the edge of the half-inch boards so that a rim of one-eighth of an inch projects above and below the flat or floor of the board itself. By turning the boards occasionally, time is saved in cleaning.

We cover the floor of the brooder with a thin layer of coffee shells or other fine litter, and place these boards on top of litter. The object of all this is to have the grit (and, later on, the feed) under the feet of the chicks, where they will find it.

It is wrong to mix feed with litter and expect baby chicks to find it. The mother hen is absent, and we all know, if she were present, how she would take a bit of grain in her bill and call the chicks to her and feed it to them one by one. We have all noticed how the chicks will walk through the feed, never noticing it, to get the kernel the hen is calling their attention to. In the absence of the hen we must place the grit under their feet, where they naturally first look for something to pick at.

The brooder is now ready for the chicks—water, grit, litter, and temperature at 95 to 100 degres, as described.

The chicks are taken, preferably in the middle of the day, in boxes, and counted as we place them in the brooders. We put fifty to seventy-five chicks to the brooder, as room may permit. We prefer fifty, but seventy-five will do well by giving them a little more attention.

In transferring them, in the middle of the day, we seldom cover them up, as they are not long on the road. Of course, if rainy or windy, a gunny sack is thrown over the box in transit.

As soon as they are in the brooders our only duty for that day is to keep the temperature at 95 to 100 degrees and keep the boards supplied with grit.

They learn to eat from the boards by picking up the shining particles of granite grit. They learn to drink readily, and the grit, water and heat keep them in condition to absorb the yolk, which must be absorbed before the digestion of grains is begun, if we would start the chicks right.

The question of heat and ventilation for the first five days is vital. We use oil lamps in the brooders, the fumes from which are carried off by a metal smokestack, and no smell from the lamp allowed to contaminate the air which the chicks breathe.

Pure fresh air, from out of doors, is conducted through a double drum heater, where it is heated before passing through into the nursery hover, and then diffused downward onto the chicks. This pure air, from out of doors, heated, and coming in on the

chicks in a constant flow, is all the ventilation needed for the first five days. The door into the next compartment, or exercising room, has cracks about it to let enough air into the exercising room to keep up the circulation and enable the heated air from the heater to come in readily. Later on—i. e., after chicks are five days old—an opening between the nursery and exercising room is opened fully, partially, or closed altogether, at the will of the operator, by a sliding door.

With the ventilation problem off our minds, we have nothing to do but to attend to the temperature. The temperature is regulated by the height of the lamp flame. When the sun is shining brightly in the middle of the day, little heat, if any, is required. It may be that a gunny sack hung over the brooder nursery door may be needed to keep the temperature down to the required point. As the afternoon advances, the lamp flames must be gradually pushed up, and when we leave them at 9 or 10 o'clock in the evening, we leave the mercury registering a few degrees higher, to carry the chicks through the cold hours before sunrise without the least discomfort or the possibility of a chill.

We start them at 95 to 100 degrees. We find that in the daytime, when active, the chick does not need quite as much heat as at night, when quiet, so we start them at 95 degrees during the day and 100 degrees at night. After the first five days we run at 90 to 95 degrees, as above explained, for a week, and then reduce temperature gradually.

The second day in the brooder we begin to feed a mixture of small grains. We used to mix our own feed, but find our time worth more than the profit which the poultry supply dealer makes on the mixture, so now use the commercial mixtures. The principal thing is to get a good clean-looking mixture, with grits and a variety of grains. This mixed chick feed we feed four or five times a day on the boards already described, so the chicks can find it under their feet, with no litter mixed with it.

After they are five days in the brooder we begin to mix the feed in light litter. By easy stages the chick learns to find its feed in deeper litter, and they will scratch to beat the band. The first mixture of feed with litter is around the boards where the chicks go for their feed. These precautions are quite necessary to prevent the loss of chicks that otherwise would fail to find the feed and slowly starve.

The second day after being put in the brooders we feed a mixture of commercial beef scraps, charcoal and baby chick grit, on the boards, under their feet, where they first learned to pick up the shining granite. We give this mixture once a day for five days on the boards, then keep a dish of it before them at all times.

We begin also on the second day after the chicks are in the brooders to feed them green stuff—anything green that is small enough for them to eat. We feed this several times a day—a little, often, is better than a lot, to be trampled under foot and rendered unfit for use.

We have never had a case of toe picking since we began feeding meat scrap and green stuff the second day after chicks were put in the brooder.

If we keep our chicks warm for the first five days, we have found the mortality between three and six weeks to be greatly reduced. We do not fear bowel trouble, no matter what is fed, if the temperature and fresh air factors are right. On the other hand, we find no scheme of feeding is worth anything if the temperature and ventilating problems are neglected, for bowel trouble will follow, no matter what we feed.

In other words, the condition of the chick is what permits the disease germs to get a foothold in the intestines. The proper regulation of the heat and ventilation for the first five days is the greatest thing in brooding. An even temperature at all hours of the day and night for five days will start the chicks with the strength to "make a live of it" provided the parent stock is vigorous and the chicks are properly hatched.

THE INDIAN RUNNER DUCK.
By Caldwell.

Most every one knows something about Pekin ducks, but not so many are acquainted with the Indian Runners. They are comparatively a new breed in this country. There are several shades of color, pure white, fawn and white, and brown and white; all are good layers, hence it is a matter of breeding for quality and egg production. They do well in a small enclosure. Nevertheless well-bred Runners are great travelers and will wander long distances in search of food. For this reason, if allowed plenty of range they will require but little feeding for a greater part of the year. They are rightly named Runners, being very active, but are always to be found at their roosting place at night.

They are the most hardy of all domestic fowls, being originally a native of the West Indies.

It is no trouble to raise an Indian Runner duckling, for when it is hatched, it is as good as raised, unless some accident befalls it.

They are reasonably immune of vermin and disease, hence no dust bath to provide for. No nest boxes; no flying over fences; nor scratching gardens,—so you can readily see that they are an economical as well as a profitable variety. No other fowl can approach them as layers, especially of winter eggs. They commence laying at four and one-half to six months of age if fed for that purpose. They lay a large white egg, which commands a premium. They eat inexpensive food and are never bothered with "cold feet," and may well be called "mortgage lifters." We take a real pleasure in caring for our flock of Runners and find them far more profitable than chickens.

Do Your Buildings Need Paint?

Examine your buildings and see if they need painting now. If they do, don't put the work off because you believe linseed oil will drop in price. There is no hope of it. Besides, the price of paint made-to-order of

Incubators and Brooders

The evidence is conclusive that the PETALUMA is the best Incubator buy that can be made. The best value for the money ever offered and is appreciated most by those who have had varied experiences with other incubators. Why? Because it hatches such large, strong vigorous chicks. More Petaluma Incubators were installed in the large hatcheries last year than all other makes combined. No other incubator in the world has a hatching record to equal the Petaluma.

Roosting and Scratching Shed House

LOUIS D. HADLEY.

One house is composed of two rooms, a roosting room and a scratching shed. The former is for the fowls to sleep and lay eggs in; the latter is used during the day time as a work-shop and feeding room for the hens.

This house, by building two roosting rooms together and two scratching sheds together as shown in drawings can be built to any length one may desire, the number of houses to be governed by the number of hens the builder intends to keep. Location of doors and windows is plainly shown in drawings; also lines are shown to indicate direction the doors are to swing. One house has three doors; should two houses be built, with the two roosting rooms together in the middle and the two scratching sheds at the two ends, there should be five doors and six windows—two double sashed windows in front of each roosting room; one single-framed window on hinges between each roosting room, and each scratching shed, and one single-framed window on hinges on outside of each scratching-shed. The roosting room of each house should be 8x10 feet and the scratching shed should be 10x10 feet. The front of the whole house should be 8 feet high and the rear should be 5 feet high.

This open scratching-shed with the floor covered with straw to a depth of six or eight inches, is simply grand for the hens during rainy weather.

This house is admirably planned as regards the roosts and nests, the roosts being at the rear of the roosting-room out of the way and where you will find the minimum of drafts, being neither close to the floor or close to the roof.

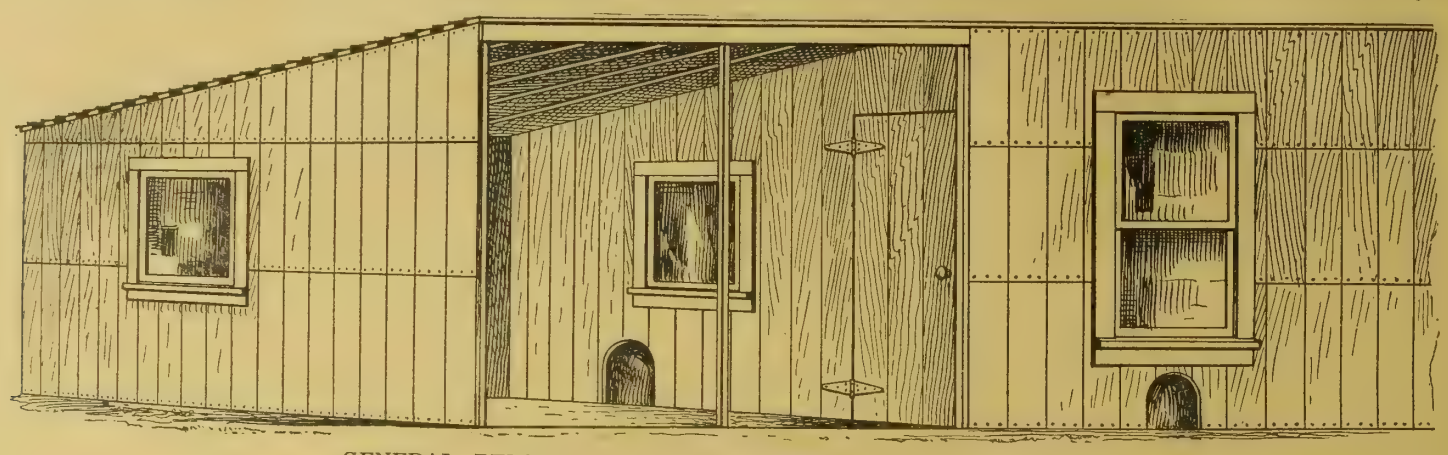
The outside of this house can be made of materials to suit your pocket-book, so long as it is made warm and tight. Plain boards covered with water-proof building paper and battened, or rustic, siding, and shingles for roof. Stick to the dimensions and build so interior will be dry, warm and arranged to ventilate, and all will be well, regardless of material used.

The top of the sills of this house should be ten inches above the surface of the ground on which you intend to build, and dirt should be filled in enough to bring the surface of the floor of dirt up to the bottom of the sills, the top four inches could be made of concrete, the top inch of surface made of fine sand and cement, and made smooth, same as cement sidewalk with two-inch hole at back of each room under the two-inch sill to allow water to run out that may at any time get in from an unexpected shower or when you are flushing out house with hose. When occupied, cement floors are covered each with two buckets of sifted clean sand, and six or eight inches of straw, roosting-rooms and scratching-sheds both, then thrown inside, by letting water stand over the entire surface about 24 hours.

The bottom sills should be 2x4, redwood or pine, halved at ends and nailed together at ends and where spliced.

These sills should set on posts set in the ground two feet. Redwood or pine, dipped in crude oil or asphaltum, or plain cedar or chestnut posts four by six or six by six inches are about right. A post should be at each corfowls will not slip or hurt themselves when jumping down off the roosts. The real value of the cement floors is in keeping out rats, skunks, weasels, etc., and preventing a blinding, stifling dust when hens are scratching in the straw for grain.

When a house is filled in to bottom of sills inside, dirt also must be put along the outside on a slant up to about the same height, so that no water will ever run towards the house, but on the contrary will always run away from the house. Before ever putting in cement floors, be sure to settle down perfectly the fresh dirt



GENERAL PERSPECTIVE OF THE LAYING POULTRY HOUSES.

VEGETABLE SEEDS

Forty years of experience in this line have placed us in a position where our recommendation is final with a large clientele. Our mail order department is perfectly developed. See our 1911 Catalog for details.

GARDEN VEGETABLE SEEDS.
Carefully selected and fresh. Complete stock.

SEEDS FOR COVER CROPS.
Our experts will advise you in selection.

FIELD SEEDS.
Such a large item that we can quote bottom prices.

CLOVER AND GRASS SEEDS.
All extra recleaned and perfect stock.

LAWN SEED AND FERTILIZERS.
We have special mixtures to suit every condition

POULTRY SUPPLIES

There are no exclusive poultry supply houses that carry a larger line of supplies than Germain's, and none that handle a more carefully chosen and reliable list. Especially striking in our stock are

CYPHER'S INCUBATORS.
The guaranteed, absolutely automatic and fireproof apparatus.

PROTEINA.
The perfectly made Soy Bean Oil Meal. Write for pamphlet.

COULSON'S FOODS AND REMEDIES.
Ask for special booklets on these quality goods.

INTERNATIONAL AND CONKEY'S FOODS AND REMEDIES.
Standard all over the country.

TOOLS AND IMPLEMENTS.
Everything the poultryman needs.

GERMAIN'S SEEDS ERMINATE

FLOWER SEEDS

All standard sorts and many fine specialties make this department the resort of thousands who want dependable seeds at the right price. We can supply the demand for varieties and quantity.

HARDY ANNUALS AND PERENNIALS.
A most complete list is found in our 1911 Catalogue.

EUCALYPTUS TREE SEED.
We are making a specialty of "The Timber of the Future."

"SUNSET" COLLECTION SWEET PEAS.
The greatest 50-cent collection we have ever offered.

TREES and PLANTS

A noteworthy feature of this department is the fact that all trees are shipped with an inspection certificate signed by an inspector of the Horticultural Commission; it is a guarantee of cleanliness and health.

CITRUS FRUIT TREES.
No finer grade of stock can be found anywhere.

DECIDUOUS FRUIT AND NUT TREES.
Including all kinds of grapes and berries.

ORNAMENTAL PLANTS AND TREES.
Palms, Shrubs, Bedding and Border Plants, etc.

ROSES.
A splendid list of the finest roses grown.

Automobile Delivery in Los Angeles

ner of each room, and one between each of these, making the posts five feet apart in front of the scratching-shed, and four feet apart in front of roosting room. Put one also in the center of each cross partition. Nail a board one foot wide along the lower half of sill, letting it drop down into the ground a little; of course you will have to dig the ground out a bit to receive it. This board should lap one inch on sill, the other inch of sill remaining to nail upper boards to. This board must be nailed tightly to foundation posts.

mediate studs can be used, two making the structure just that much stronger. By using all 2x4 material for all studding it makes it come out better where you intend ceiling inside with matched boards.

Cut the top end flush with outside of plate, and cut the lower end so that it will project about eight inches, having it mitred that a gutter may be nailed to it.

The rafters over the house can be placed two or three feet apart as the builder desires, of course the closer they are put, the more steady and

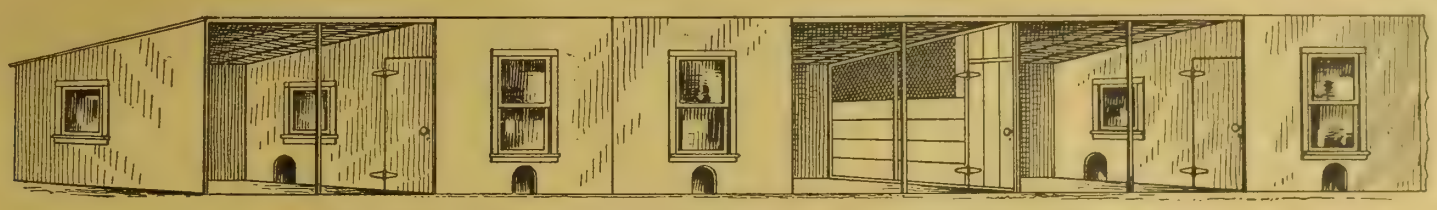
on give the whole a second coat of paint. For front of roosting-room have a window frame set in to receive a lower and upper sash, that they may be lowered and raised as desired.

The windows can be composed of one pane of glass each, or several small panes. Make the partitions between roosting-rooms and scratching-sheds from the top of bottom sills up for four feet, of boards, the rest of space of poultry wire to roof, leaving two or three feet space at front of house for the door, having a 2x4 stud with board up and down to swing door

doors open when cold.

The dropping-board or roost platform is made of matched boards, is three feet wide and made just long enough to slide in between the partitions in roosting-room on two cleats about three inches wide and three feet long, nailed securely to the sides of roosting-room partition.

Six inches above these cleats for the dropping board to slide in on, nail one more cleat on each partition opposite each other for the roosts to rest on. Before nailing the cleats for the roosts onto the partition, measure off



EXTERIOR VIEW OF SCRATCHING SHED AND ROOSTING ROOM.

Plates of 2x4 scantling, being a duplicate of sills, should be halved and nailed together at corners and splices. For the front of the house cut the required number of studs seven and a half feet long, and for rear of house cut studs five and a half feet long. These studs are cut from 2x4 scantling, one for each corner of roosting room and scratching-shed.

Toe nail these studs onto sills and on top of them spike the plates.

In the front of each scratching-shed set an intermediate stud of 2x4 material, also for front of roosting-room, set the proper distance apart to receive the window frame, put two studs 2x4 scantling.

For the rear of each roosting-room and scratching-shed one or two inter-

stronger the house when finished.

Should you intend to cover sides of house with sheathing paper and roof it with roofing paper instead of shingles, all your outside boards should run lengthwise of your house. Cheap boards can be used for this way of building, avoiding boards with bad cracks and holes. In putting on paper lap each piece about three inches. Put sheathing paper on first, then roofing paper on over this, running paper lengthwise of building, putting tin head nails about three inches apart and about one quarter of an inch above the edge of top lap.

Put on battens eighteen inches apart. Before putting on the battens give them a coat of paint, also the paper, then, after battens are nailed

on; this same studding acts as a support between rooms. The single sash windows hung on hinges and set between roosting-room and scratching-shed should be set in a single frame hung to swing into roost-room and secured by a spring catch when shut. Door should be hung so as to swing in and towards back of scratching-shed, furnished with a hook in door and eye in partition so that door during warm weather can be left open and fastened to prevent wind from blowing it back and forth.

A little opening under front window leading into yard and one of the same under window between roosting-room and scratching-shed furnished with slide doors permit of exits for birds without the necessity of keeping large

ten inches from the end of the cleat that is to go to back of room, saw out an inch deep and three inches wide which is to be a grove for the 2x3 roost to set in and hold in place. Fifteen inches from this groove or notch, saw and chip out another for the second roost. This makes the roosts fifteen inches apart, and the back one ten inches from the back wall. The roosts should be made of 2x3 scantling sawed the right length to set on these cleats just above dropping board and should be slightly rounded on upper corners. When cleaning droppings off the boards the roosts are lifted from their sockets and set back against back wall, one on top of the other. The nest box is pretty plainly illustrated and gives a

"SUCCESS" Incubators

Everybody Knows

THAT EVEN HEAT and the RIGHT amount of warmed fresh air is what hatches eggs. This can be had in a "SUCCESS" Incubator just the same as in any other well made redwood case labeled Incubator. Don't think because some companies use a pretty label and a big price that you will get any more value than in the "SUCCESS" Incubator which I sell at these very low prices.

We Pay the Freight

Buy from me at wholesale prices

Which would you rather do, buy from a company that sells through agents and tacks on 25% to the real value of the Incubator or buy from me at first cost? Any company that sells through an agent has to give them 25% to 35% of the price, or they would not sell the goods, that is plain. I do not sell through agents. I keep no books, sell to no one on credit, have no losses for you to have to stand a part. I sell to you at wholesale. My price list proves it. I sell a hot water, three pipe system machine, double walls, double top, slatted egg trays, compound heater, complete with removable nursery drawers, stained mahogany color with three coats shellac, and then pay the freight on the machines. I can do it and still make a profit. I own my own buildings, pay no rent, use no high priced useless office help, and everybody works. If you are with me, get my free book today, 48 pages. It tells the story. Our 64-page Pioneer Hatchery book tells the story of the largest baby chick concern in the world. It's worth while. Send your name to me today.

———Experience

I can show you quick where we get it, when you get my book. My business doubles year after year, because I make good Incubators and sell at the right price.

We hatch 100,000 eggs every 21 days.

My heaters cost MORE

Than any other hot water heater used on any Incubator whatsoever. It has three pipes, hot water goes around the outsides of the case first and returns through the central pipe. The copper boiler on the 612-egg size is 10 inches long, no other is made that long, and three pipes cost more than two. No hot air Incubator on earth will run as even as a first-class hot water Incubator.

INVESTIGATION is all I ask. Send for the book today.

60 Egg, - - $9.00
130 Egg, - $14.00
360 Egg, - $25.00
612 Egg, - $40.00

WE PAY THE FREIGHT

E. E. McCLANAHAN

108, 110, 112, 114, 116, 118 East 8th Street Los Angeles, California

good idea as to what it should be and how it should be made, it is to be made six feet long by fourteen inches wide (inside measurements), and then divided equally into six nests, hinged at the bottom in a long door to be shut up and caught by spring catch at top when shut. This nest is placed directly under the dropping-board, having a one-foot space at each end for hens to go in and around to nests.

Placed in this manner the nests are partially dark and suit the whims of a hen when she wants a quiet, secluded spot for a nest to lay in.

A good plan is to have two doors made, each of light weight, matched boards with a window of glass or celluloid in each, hung to top of front of scratching-shed on heavy hinges so that door can be swung in and up against roof out of way during mild weather and secured very strongly in a way so far as to be practically impossible for them to fall down accidentally and hit some child or chicken, 'tis also good to have doors swung on double acting hinges that the doors can also be swung out and up, and fastened when out and up to a 2x4 scantling, the ends of which rest on three 3x4 or 4x4 posts set in the ground at just the right distance from the house so that lower end of door will just reach to the 2x4 resting on the posts. Two of the three posts should be set opposite each corner of scratch-shed, the third post directly opposite the intermediate stud in the center of front of shed. When fastened out and up, the doors should be supported on strong buttons fastened with bolts run through middle of 2x4. Doors should just clear the 2x4, then as door goes up past 2x4, the large wooden buttons should be swung around and allow doors to rest on top of buttons. There should be two doors to each scratch-shed, one should have a cleat on one edge extending beyond it two inches, along the edge at intermediate stud.

Other door should be let down first and fastened, then let door down with cleat on it which will extend 2 inches over first door, making it tight and keeping out bad weather. A twelve inch board should be at bottom of front of scratching-shed to prevent straw being scratched out of shed into run or yard.

Cyphers Incubators and Brooders

The Leading Hatchers of the Pacific Coast

Cyphers Standard Incubators

Ten years is ample time to prove out an Incubator. To prove whether the statements of its maker are mere "claims"—or are founded on ***absolute facts.***

Cyphers Incubators and Brooders have been out here on the Coast for ***10 years of hard and constant test.*** You will find them today on the farms and in the plants of the most successful poultry raisers from one end of the Coast to the other, and they have given a good account of themselves. They have proved that they are perfectly adapted to the conditions and requirements of the Pacific Coast climate. We've just gotten out our new Year Book and Poultryman's Guide for 1911. It presents a lot of interesting Pacific Coast evidence. We will send you scores of letters from poultrymen who are your neighbors—poultrymen you know—and who know incubators. Read these ***sample*** letters. We have many more like them:

Greenwood Poultry Ranch, Monterey, Cal., Aug. 2, 1910:—"During the season just closed I have used 4 of your Incubators. Have hatched close to 6,000 chicks. I am perfectly satisfied with them and shall use more the coming season. I find them almost perfect in regulation, and if I should ever have a poor hatch, I would blame myself and not the machine. Very truly yours, FRANK GREENWOOD."

J. Leonard Nillson, Route 2, Box 145, Sacramento, Cal., wrote us Sept. 16, 1910:—"Having been in the poultry business several years, and having tried various makes of incubators, I am pleased to report that for simplicity of operation and the best hatches, the Cyphers cannot be surpassed. I have never had a hatch less than 83% of the fertile eggs, and the chicks hatched in your machines are always strong and well developed. Will install ten more of your No. 3 machines the coming season."

H. L. Miller, San Jose, Cal., wrote us July 22, 1910:—"I took off three hatches of chickens from 244-Egg Cyphers, bought of you this year. Showed an average of 85 per cent of the fertile eggs, and succeeded in raising 98 per cent of the chicks. Was a beginner in the business."

Hatch After Hatch—The Real Proof

It's because Cyphers Incubators and Brooders are not toys—not "bargain" offer make-shifts—but ***real,*** substantial machines of ***permanent*** value—that they give such remarkable results as ***continuous*** hatchers.

In the ***long run,*** the Cyphers is the most ***economical*** incubator on earth. And it will mean money in your pocket—time, eggs, and endless worry saved—if you buy a Cyphers ***first*** instead of last. Don't "experiment" your way up to Cyphers quality by trying out one after another of the cheap, inferior kinds. Cyphers Incubators are used and endorsed by more Government Experiment Stations, by more large Poultry Plants, by more Fanciers of National reputation ***than all other makes combined.***

Cyphers Incubators and Brooders are ***fire-proof*** and insurable—are approved and ***labeled*** under the "Rules and Requirements" of the National Board of Fire Insurance Underwriters.

Cyphers service is another big feature! We are right here on the Coast to give ***prompt*** and careful attention to your every want. Our Oakland location means a ***big saving in time and freight rates to you.***

But write for our ***big free book.*** 212 pages! Full of just the ***information*** you need about America's Billion Dollar Poultry Industry. Helpful, profitable, inspiring. Illustrated with pictures from photographs showing hatches ***actally made*** and fowls raised by Cyphers Company methods. Famous poultry plants, prize-winning birds, etc. It also tells all about Standard Cyphers Incubators and Brooders, and more than one hundred Standard Poultry Supplies. Write for it today.

How to Raise Strong, Healthy Poultry

H. C. SCRUTTON.

This article is intended, not for the experienced polltryman, but for the beginner in a small way who has just got the fever, but who is nevertheless anxious to gain his experience at as little cost as possible.

The most important poultry question for the beginner is "How to raise chicks." It can be done successfully in many different ways, but at the same time for the beginner especially some ways are easier than theirs.

There are three different ways of obtaining chicks—hatching with hens—hatching with incubators and buying the chicks already hatched. This last way is the best for the beginner in his first season. Make up your mind when you want them, anywhere between January and June, and send in your order to some reliable man. Give yourself plenty of time to order your brooder and put up your house, getting this done if possible before you order your chicks, which will enable you to think out all your arrangements for their comfort beforehand.

In selecting your brooder get some well-known make which has given satisfaction in this part of the country. Get the brooder large enough—for instance, if a certain make of brooder is said to hold 100 to 125 chicks, do not put more than 100 chicks in it. It will no doubt hold the 125 chicks at the start, but chicks grow and unless some of these die they will get overcrowded later. Don't assume they are going to die—start them right—and raise them all or nearly all.

Having got your brooder selected, the next thing to do, rather it should be done before getting the chicks, is to plant some lettuce, and lots of it. It may seem a luxury to grow lettuce for chicks, but there is nothing like it at the start, and later they can have some coarser greens, such as kale, cabbage or alfalfa. Sow enough lettuce to last them for a month, and see that at the end of that time they have either more lettuce or some other green feed ready for them.

The next thing to do is to get your brooder house ready, and your brooder placed in it. Have house with three sides tight and the front open to the south. Have an eight-inch board at bottom of open side with some netting above and a protecting roof overhead to keep off the weather.

Place the brooder in handy position, in accordance with the maker's directions, and put plenty of sand over the floor of brooder house and in the brooder as well. On top of this put a liberal supply of cut straw or any other clean litter you may have. Place a little box with oyster shell, grit and charcoal close to the brooder and also a small chicken water fountain.

For the first two or three days after the chicks arrive do not give them the full run of the brooder, but confine them to a small space immediately in front of the brooder, so that they will learn to run in and out, and to enable you to see that they all get feed and water.

Now comes the important question of feed, and this is one of quality, not of price. Get the best make of chick food, consisting of crushed grains, etc., which you can. Cheap cracked screenings may be all right for older chickens but they are apt to be dirty and unsound, and the risk of feeding a cheap feed to baby chicks is too great. It simply won't do. Therefore get a good, clean chick food containing a fair proportion of steel cut oats in it, and pay the price.

When you receive the chicks, if they are not long out of the incubator, they can be kept in the brooder most of the time, the first day they need nothing beyond a drink and a little grit. The second day see that they all get out for a feed and place this feed on a small board where all can see it. As soon as they all get used to feeding, throw the chick food on the litter and make them scratch for it. As they get older it can always be thrown in the deepest part of the litter, so as to keep them working all the time.

If you adopt this plan and have a good brooder house there is no occasion to let them outside for the first two or three weeks. This keeping them in is contrary to some people's ideas, but I prefer it as the safest plan, provided you keep them busy with plenty of litter.

With the open front house they have plenty of air, but are kept away from rain and wind.

With these suggestions the beginner should be able to raise his first flock with a minimum of loss. He will then see there is really money in the business and with his own experience, be able to branch out in a larger way.

BURLAP CHICKEN HOUSE.

By Mrs. C. D. Hubbard, San Fernando.

The following outline description gives a poultry house for California conditions which is the equal of many far more expensive ones.

We carefully save all burlap sacks and with a bit of second-hand lumber can construct poultry houses with practically the only outlay for roofing. Make two frames, one for the sills and another for the top. The sills should be of 2x4, and the upper frame may be of 2x3 and of pine. The dimensions of the two frames should be identical. The uprights may be of 2x3, those for the front being 6 feet high, and have the slope of the roof bring the eaves about 5 feet from the ground. The house should front to the south with door on same side. The only framework necessary is sufficient to hold the burlap sacks which are used without cutting open. The front should be covered with wire netting, as should the door. To prevent direct draft on the poultry the front may be burlaped to the height of one grain sack. This may be sowed or pinned into the wire netting, using nails in lieu of pins. The cheapest roof, and a good one, is made of corrugated iron.

The perches should not be more than 12 or 15 inches from the ground. If too high, the birds are liable to injure their feet in jumping off, causing the formation of a corn-like growth known as bumblefoot.

LAY AND LIE.

The teacher called the grammar class,
One bright November day,
And said: "My children, now you know
The hens they sit and lay;
So tell me what the people do—
Now think right hard and try."
And then a sorrel-headed boy
Yelled out: "They sit and lie."

Truro Daily News, N. S.

If there is not plenty of grit in reach of the fowls, see to it that it is provided. Oyster shells are good and may be easily obtained in many sections. The fowls will not consume the food economically without sharp grit to grind it up.

TREES

The Right Time To Plant is Now

Let Us Figure on Your Requirements.

Never before have nut trees been planted so much as they are now. As a permanent investment, they cannot be excelled.

Nuts

Getting Eggs During Winter Months

W. E. EDWARDS.

Much has been written on getting eggs in winter. Although we have never written anything on the subject ourselves before, except to give our inquiring customers what information we could along this line and help them put their flocks on a paying basis, we can say that we are highly successful along this line and have built up a heavy laying strain.

We find it is generally in the way their stock has been reared and fed, though sometimes it is the fault of the stock. Many people cross their stock with all kinds of mongrels they can find, thinking this will increase their egg yield. This is an old fogy idea that has long been exploded by many experiments conducted through the world.

A pure bred will lay infinitely more eggs per year than any mongrel. In order to get most eggs in winter, it is very essential to get the pullets out early and force them through rapidly to maturity and get them started to laying early in the fall and keep up a persistent humoring by making everything as pleasant as possible for them, thereby keeping them contented and in good laying mood and not allowing them to be frightened. This will materially decrease the egg yield if allowed.

At one of the women's clubs, sometime ago, discussion was up as to the training of children, when the training should begin, etc., and one lady said that she considered the proper time to begin their training was a year before they were born! I would say that that would be a good time to begin to prepare our winter layers. Commence with strong, vigorous, heavy-laying parent stock, and the rest is easy. Chicks from stock mated up haphazard will probably be weakly and get stunted before grown and will never amount to anything.

In order to get many eggs from old hens in early winter it is necessary that they be carried through the moult in as strong and vigorous a condition as possible. Do this by giving them the proper food to keep up their system in good shape and that will grow a new coat of feathers as quickly as possible, when they should again have their egg-producing material in abundance.

But it makes no difference how well you care for the hens, they will never produce as many eggs in early winter as pullets. It is the preparatory work that brings about the conditions by which we get the winter eggs that we all seek so eagerly while eggs are at their highest.

The flock should be bred up to as high a state of egg production as possible, which we have proven can be easily done, by proper selection and mating. Still, much depends upon the feed, feeder, housing, etc. They must have the right food at regular hours and have it abundantly. Too many people feed poorly, i. e., underfeed and do not give the proper egg producing materials. In order for biddy to do her best she must be highly favored by having clean, well-ventilated, peaceful quarters and have variety, charcoal, grit, shells and fresh pure water should be at her command. We feed a mash once daily which consists of between fifteen and twenty ingredients properly compounded, and give a variety of grains in the litter to scratch for, which gives plenty of exercise during the day and in the evening give corn, wheat, oats and sunflower seed mixed, and let them eat to the limit. Always send a hen to bed with a full crop if you wish her to lay. It is the heartiest eater that is the best layer.

It is not necessary to know Hoganism in order to select a good layer. All that is necessary is to develop your birds rapidly and get a "sawmill" appetite onto them, and I assure you that you won't have many that you would need to weed out, as they will fill out well from comb to lay-bone.

In a future article I will give you more along this line. We have experimented with scratching pens much, both East and in California. While we use them quite a great deal here still, we do it mostly for the exercise it gives the chickens and not altogether for the eggs it produces, as the ones who have no scratching pens, lay as many eggs as the ones with them.

Prof. J. E. Rice, poultry expert for Cornell University, in an address before the students of the agricultural college of the University of Missouri, made the statement "that hens with short toe nails that were worn off by scratching were the greatest egg producers." (This shows that they were industrious.) He is right. For in that country or in any other cold country with their changeable weather, biddy has to almost scratch her nails off to keep warm, and the scratching pen is a necessity; but not so in California, as she has the orchard and meadow in which to scratch and can do it in the sunshine. I always earned every egg I got during the winter while in the poultry business in the East.

Open front houses are best when made free from drafts. They should have curtains to drop down over opening, on cold, rainy or windy days.

The whole thing can be summed up in a very few words. In order to get eggs in winter, we must have strong, vigorous, well-bred stock of a heavy laying strain. They must be properly housed, and fed scientifically with the proper foods at the regular feeding time, fed in abundance; but the heaviest feed at night.

A GOOD POULTRY HOUSE.

John D. Mercer.

A prominent physician of Los Angeles asks for information that will enable him to build a small poultry house that will hold about a dozen fowls and one suitable for this climate. This is a question that is frequently asked. In fact it is the most important of all subjects for the poultry-keeper, and one that is usually answered in a meager and very unsatisfactory manner. The ideal poultry house for the average keeper of a few fowls should be one that will properly shelter, assure health, be cheaply built and easily kept clean. These are the essential points to be considered and the following description, with illustration, we hope will be of service to many.

We recommend this style of house for all sections of Southern California, except such elevated locations that are subject to cold winters. This style of house will keep fowls healthy at all times and with a minimum amount of care free from vermin, if

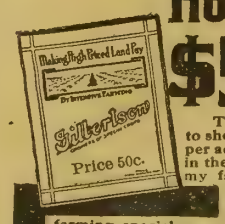
Crop Specialist Tells

How To Make Your Land Pay

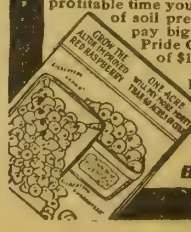
$500 TO 1200 Per Acre



That may sound like a story—but I am here to tell, to show and to prove that a profit of from $500 to $1,200 per acre is within the reach of every farmer or grower in the country. I have made this remarkable record on my farms for several years—other farmers who have adopted my methods are also succeeding—the same success is within your reach. The secret of this wonderful profit is scientific and intensive farming, special preparation of soil and the growing of special crops.

Write For My Two Free Books

Book No. 1 is my intensive farming book, not a catalog, published to sell for 50c; send and get it now free; tells of my experiments and experience for the last 32 years. It has taken 32 years to write and to complete it. If you will at least spend 32 minutes reading it it will prove to be the most profitable time you ever spent. This book explains my special method of soil preparation, how to rotate crops, how to make your land pay big profits as I have done by growing my Grandpa's Pride Globe Onions which have produced an average profit of $15,000 on 40 acres and other special crops.



Book No. 2 gives the history of the Alton Improved Red Raspberry which has produced an average profit of $1,200 per acre on account of its remarkable size, flavor, long fruiting season and vitality.

Write for my books today, they are free and will interest the man who is looking for big profits.

A. O. GILBERTSON, CROP SPECIALIST,
Box 619 Mason City, Iowa.

I Have Farmed For 32 Years

During this time I have experimented, my one aim was to produce special crops that would be out of the ordinary in quality and profit. One of the most successful experiments was with raspberries. Instead of growing the ordinary variety and taking an ordinary profit I propagated a special variety now known as the Alton Improved Red Raspberry that has stood the winters of Northern Minnesota, North and South Dakota and even as far north as Canada, without the least winter protection. The Berry is especially remarkable for its size and delicious flavor as well as for its long fruiting season, which on an average extends over a period of three months. If you only have a city lot or if you have a farm investigate this wonderful, large, delicious berry now.

Modern Methods of Artificial Incubation

HENRY LANGENSCHWADT

Have you ever turned your thoughts to what life really is? How great is the depth of the subject when we begin to think about it. How wonderful and mysterious! We start to investigate, trying to find what causes it and the growth of the being, and we no sooner think we have one problem, may be the solution of it, than others are encountered perhaps more difficult than the one we started out with.

The ordinary hen's egg is what we will consider now for a few minutes. It is familiar to almost every one as an article of food. It is the life side of this egg we wish to inquire into. Under right conditions life is started in the egg and will grow in the short time of three weeks reproducing the parent body. Nature in her course provides for the bringing about of this.

The mother hen it seems just applies warmth to the egg and the life develops and grows, certainly, provided the egg has been fertilized. Man found out that this development could be brought about without the hen doing it, in other words, artificial incubation or hatching. This was learned centuries ago. Yes, and it seems was carried on on as great, if not greater scale than it is at the present time.

The incubator of the present day, though, seems to have had its beginning about a century or so ago. Different sorts of machines were brought to the attention of the public and demonstrations given how eggs could be hatched without the hen. It is only within the past fifty years that this invention, the incubator, and its manufacture was brought to a commercial basis. The increase in the use of the incubator has been very great during the past fifteen or twenty years so that today it is quite common and looked upon as something we could not get along without.

Artificial incubation has not failed to bring some great problems before the poultryman. The hen, it seemed, just kept the eggs warm, about the temperature of her body when she was broody or in conditon to hatch the eggs. Cases are known where eggs have been hatched when they were maintained in different ways at right warmth. However the hen in her natural state hatches all or nearly all the eggs she starts out to incubate. When we use the artificial method or incubator we do not meet the same results. After taking out the infertile eggs that have never contained the germ of life only a percentage are hatched in the incubator or machine as we sometimes term it. Sometimes that percentage is very small. Not alone in point of number of chicks secured but also in their vigor and vitality do we find a difference in the artificial and natural methods.

To successfully hatch eggs artificially we want to duplicate the same conditions present when the eggs are under the hen. This as we have learned and are learning more and more, is not so easy a matter as it apears. It is not only a certain degree of warmth that is required. There is humidity combined with heat and other factors as to the eggs upon which the hen is setting. Then the eggs are not always lying in the same position. They are moved more or less often. So we find artificial incubation to give us good strong chicks is not nearly so simple a process as it seemed when we started out.

Investigation has revealed much about incubation and performing it artificially, but there is much more to be learned about it till we can succeed as well as the hen does. The government has taken a hand at the different experiment stations in the endeavor to solve some of the problems. There has been some valuable work done, but not what could be accomplished. The writer believs if these investigations were taken up and done by men that are practical great good could be accomplished. What do you think of turning over to a chemist the investigation of chicks dead in the shell found in incubator hatches? Such a case the writer knows of. The chemist may be needed to do a part of the work, but after all should he not do it with or under a practical man who knows more about the hen and her habits and poultry work in general. This may not bear directly on this subject, but we believe it would be well for the average poultry man to be interested in what government work is being done and interest it in doing more.

The incubator is often blamed when it is not so much at fault as the eggs. You must have good, hatchable eggs before you can expect results. When the hen cannot hatch some eggs, how can you expect the incubator to do so. Yet this is often the case. To secure good eggs you must have breeding stock that has proper feed, care and attention.

To operate your incubator follow the directions that come with it. The manufacturer ought to know best how to get results from his make of machine. The construction is so different that the method of running one make of incubator to get good results cannot always be applied to another make and expect the same results.

There is a great difference in the chicks from the same kind of eggs hatched in different makes of incubators and by differnt persons. It is really a business in itself, this hatching. It must be learned by experience and practice, and it cannot be expected that one can learn all about it by one or two hatches. In fact, we believe it will be for the best of the poultry industry if all hatching were done by persons devoting their whole time to that work. It seems the trend is more and more that way as time goes on. The experienced hatcher knows the eggs, and he can watch their progress during incubation much better than the person taking off only a few hatches a year. He will secure more and better chicks if he knows his business.

The incubator is not yet perfection. There is room for improvement. But whatever improvements are put upon an incubator, it should be thoroughly tried and tested before putting upon the market. So many incubators are just made to sell. Changes in construction are made from year to year that the writer knows in some instances were for the bad rather than good. Former models give better results than recent ones put upon the market. Select a machine that has been well tried and tested.

It takes good hatchable eggs, a good incubator and then the person must know how to run it, and good, successful hatches are assured. They may not be as large in percentage as the hen would bring off at all times, but then there is nothing but has its weak and good points.

AGAIN EGGS BY THE POUND.

According to a press dispatch under date of January 15, Senator E. K. Strowbridge of Hayward has introduced a bill, which if enacted into a law, eggs will no longer be sold in California by the dozen, but by the pound. The measure was drafted by the Hayward Poultry Produce Association, which assures Senator Strowbridge that all other poultry associations of the state want such a bill passed. The first section of the bill provides that all poultry produce, of wild or tame origin, must be sold by the pound weight avoirdupois. The second section directs that chickens, turkeys and other fowls which are produced or introduced into the state shall also be sold by the pound. The third says that all eggs of chickens and ducks shall be disposed of in the same way.

The agitation for this reform in their disposition is not by any means of recent date. Iowa has such a law, and we believe the same is true of other states, but for some reason it has never become the practice. Viewed on moral and economic grounds it has everything to commend it. A dozen large eggs possess a value over a dozen small ones; likewise a dozen fresh hen fruit are better than a dozen cold storage eggs, not only in eating quality, but also by reason of more weight. Breeds and varieties producing the larger eggs, would under the operation of such a law, take precedence over those sorts producing the smaller product; the only hope of the small egg hen would be to lay a larger number.

Poultry breeders and consumers quite generally favor the law; the chief objection would come from the dealers. The system as at present constituted has become so thoroughly intrenched and has so long been a custom, that some inconvenience would at first be experienced, and at the same time it would require a readjustment of values all along the line, not only as to all the market classifications of hen fruit, but also as to the commercial standing of breeds and varieties. Under such a dispensation the Minorcas would undoubtedly become greatly popular.

In view of these facts, The Cultivator is firmly of the opinion that the only just and equable method of selling eggs is by the pound; it is alike fair and just to producer and consumer, and would at the same time give credit to the bird producing the largest quantity of product by the scales instead of by the dozen, the latter being often less in actual quantity of manufactured product.

CAN EGG-PRODUCTION BE STIMULATED?

As a general proposition we have not "gone heavy" on the idea that egg-production can be much stimulated beyond what good care and wholesome feeding will bring about. That we are not alone in this position is possibly best shown in the fact that but few commercial breeders resort to stimulating foods and condiments with a view of increasing egg-production. In the light of these facts, it is indeed interesting to learn that in England a liberal allowance of mustard is regarded an essential in the ration in order to secure the maximum number of eggs. To prove conclusions the Poultry World of January 6 reports the results of some interesting experiments in feeding for eggs with three pens of Buff Orpington pullets of six birds each, all of which were given the same size house, yards and care. One pen was fed in the ordinary way; the second pen was given the addition of Capsicum, or ground red peppers; the third was given mustard instead. The experiment covered a year's time. When the returns stood thus—"Ordinary" 914 eggs, value £4 17s. 6d.; "Capsicums," 905 eggs, value £4 15s. 8d.; and "Mustard" 1023 eggs, value £5 15s. 2d. Taking the year round, the "Mustards" showed an extra profit over the "Ordinaries," of over 2s. 4d. per bird. A curious feature of the test was seen in the fact that the "Ordinaries" beat the "Capsicums," so that the cost of the Capsicums was a dead loss, apart from the fact that the birds fed on them laid the smallest number of eggs during the year.

The tests, however, were carried still further, to include fertility and hatchability of the eggs, and finally the influence on the health of the hens. The pens were mated on March 1st, and thirteen eggs were set from each on March 14th. The results yielded were "Ordinaries" fertility 84 per cent, hatching 90 per cent; "Mustards," fertility 100 per cent, hatching, 92 per cent; "Capsicums," fertility, 84 per cent, hatching 100 per cent. The chicks throve well, and on August 4th three cockerels from each pen were killed. The "Ordinaries" averaged 4 lb. 6 ozs., "Capsicums" 4 lb. 11 oz., "Mustards" 4 lb. 8 1-3 ozs. Here the mustard diet came in for second place. At the expiration of the twelve months two birds from each pen were killed and subjected to post-mortem examination. All six birds were thoroughly healthy, the "Capsicums" were slightly pale in liver, but not seriously so, whilst all the other organs were absolutely sound, the "Mustards" and the "Ordinaries" were in the pink of condition.

THE PRICE OF SUCCESS.

In its last analysis there is nothing difficult in the way of successful poultry culture: the two big factors are good sanitation and wholesome feeding. Coupled with these one should possess a love for the bird and a pleasure in studying its wants. A punctuality to details is of course essential. Dr. George B. Morse in a late address before the American Poultry Association at St. Louis, laid down seven rules which spelled cleanliness from within and from without. Here they are—tack them up in the hen house, observe them, and you will be quite apt to "go straight:"

"Clean out by giving Epsom salts.

"Clean up by spreading powdered slaked lime.

"Clean the water supply by addition of permanganate of potash.

"Clean the food by preventing contamination or by applying heat.

"Clean the eggs by dipping them in 90 per cent alcohol.

"Clean incubators and brooders by scrubbing with boiling water and good old-fashioned kitchen soap.

"Clean breeding by breeding from the youngest stock consistent with the requirements of good breeding.

AN OUTRAGEOUS LAW.

Even some of the best lawyers of the state have been unaware of a vicious law passed by the state legislature of 1907. It provides that the orchardist or gardener may not secure damages for depredations of live stock unless his premises are surrounded by "a substantial fence or other enclosure."

The Cultivator receives this information just as it is going to press, so cannot give it the attention it deserves. We quote, however, one paragraph from a letter from Attorney E. L. Payne:

"I therefore conclude that no damages can be recovered for trespass committed by animals, except under the statute of 1907, as that law repealed prior statutes giving right of action for damages, and therefore no damages can be recovered unless the land is fenced or enclosed, as provided by that statute. Such a state of affairs is certainly outrageous, and calls for remedial legislation."

The people of the Antelope Valley, who are making homes on comparatively new land, and may be put out of business if this law stands, are taking up the fight for repeal of the law.

Senator Lee C. Gates has the fight in hand at Sacramento. Every subscriber of the Cultivator should write him, and to the assemblyman and senator representing the district in which the subscriber lives, and urge the repeal of the trespassing law passed March 23, 1907, whereby the owner of, or one in possession of land is required to fence in order to secure any damage against trespassing stock.

A DELUSION AND A SNARE.

People having to do with chickens, and especially those about to embark in the poultry business, should beware of the 200-egg hens now so freely advertised in the poultry press; likewise, the proverbial grain of salt should not be forgotten when reading of big annual profits per hen. We are not trying to decry the bird with the fine egg record,—far from it. We not only glory in her prowess, but we worship at her shrine, and burn incense at her nest. But we deny her the capacity to produce her like, no matter what the mating may be. In other words, the 200-egg hen is undoubtedly a tangible fact; but the 200-egg strain of fowl it still in the making and a matter of the distant future.

Likewise, let us utter a word of caution as to the fabulous profits to which certain advertisers give publicity. Margins of from $3 to $6.40 per year per hen may be possible under unusual culture and rare conditions of selling breeding stock and eggs for hatching, but they are entirely unknown to the average flock the country over. Indeed, an average of 150 eggs per hen per year covering the run of a flock is a handsome return, especially if it be one of 300 head and upward. On such a basis a net return of $1.50 to $2.00 per bird is not unreasonable. The force of this statement will be realized, when we allow that the egg in nature's laboratory represents a chick—in other words, the hen laying 150 eggs reproduces 150 of her kind, if fertility in each is allowed. That is certainly going some.

Nature is niggardly in the production of prodigies, and with her life is cheap. She creates millions of men to produce a Caesar, a Napoleon, or a Lincoln. Likewise she breeds numberless horses to bring forth a Dexter or a Goldsmith Maid, the progeny of which give traces of ancestry, but scarcely ever perfect duplicates. The same is true of the 200 and 250-egg hen.

DEMONSTRATION TRAIN.

The third demonstration train trip tours the upper end of the San Joaquin Valley beginning next Tuesday at Westley. The dates for the trip are: Jan. 31, Westley, Crows Landing, Newman, Gustine; Feb. 1st, Volta, Los Banos, Dos Palos; Feb. 2nd, Kerman, Ormus, Lillis, Armona; Feb. 3rd, Lemoore, Hanford; Feb. 4th, Visalia, Traver, Kingsburg; Feb. 5th, Sunday, rest at Fresno; Feb. 6th, Selma, Fowler; Feb. 7th, Malaga, Madera, Fresno; Feb. 8th, Clovis, Sanger, Reedley; Feb. 9th, Dinuba, Exeter; Feb. 10th, Lindsay, Porterville; Feb. 11th, Bakersfield, Delano, Pixley and Tulare.

FARMERS INSTITUTES.

J. B. Neff, conductor of Farmers Institutes for Southern California, announces institutes as follows: Etiwanda Feb. 13th, Rialto Feb. 14th, Ontario Feb. 15th, San Dimas Feb. 16th, Placentia Feb. 7th.

Agricultural News Notes of the Pacific Coast

Northern California

Some sections of Yuba county report devastation from jack-rabbits.

An Eastern syndicate has under consideration the taking over of the Los Molinos Land Co. in Tehama county.

The Sacramento Valley Irrigation Company has commenced subdivision of the Chambers tract in Glenn county.

Extensive planting of seed and trees is being made on the California National Forest, the seeds and nuts being sent from the forests in Colorado.

Sacramento milk handlers, especially some restaurants, have been brought on the carpet by the state dairy bureau for selling watered milk.

East Side and West Side Sacramento Valley boosters are in conflict as to a state highway to be constructed with funds derived from sale of the $18,000,000 bonds.

A 5000-inch filing has been made on waters of the Sacramento near Red Bluff, the water to be taken from the river by pumping and used in Tehama and Glenn counties.

The Davis almond growers association held its annual meeting on January 9th, having the largest attendance of any former meeting. Mr. J. W. Anderson was continued as secretary.

The dairy production in this state during 1909 aggregated in value $13,186,044. This was increased in 1910 to $14,403,798. The total dairy products of the last year were $28,256,609.

The Madeline Meadow Co. has secured storage possibilities and will conserve water to the extent of 40,000 or more acre-feet to irrigate lands in Lassen county.

The highest price quoted for butter in the San Francisco market was for the week ending December 1st. The average for that week was 36.83 cents. The receipts for that week aggregated 166,200 pounds, while in some of the weeks in April it went as high as 454,300 pounds, and the average price at that time was about 25 cents.

The annual meeting of the Sonoma County Farmers Mutual Fire Insurance Company was held last week and a board of directors was elected as follows: John M. Given, Forestville; A. E. Burnham, Healdsburg; Carl Petersen, Geyserville; D. R. Hill, Windsor; G. N. Sanborn, Sebastopol; P. C. Jones, Bloomfield; J. Sorensen, Petaluma; W. Evart, Penngrove; A. P. Martin, Two Rock; G. W. Smith, Santa Rosa.

Central California

Pleyto, Monterey county, is working for a vegetable cannery.

The extent of vineyards of Fresno county decreased during the past year. Some vineyards are being reset with figs.

Those interested in horticulture from all parts of the state are submitting new bills to the state legislature.

Nevada potatoes have been found infested with eel worms and have been quarantined by the state commission.

A Lindsay orange grower thinks he has secured earlier coloring of oranges by the use of sulphate of iron in his orchard.

The Fresno Republican reports that plantings of figs and olives will be more extended than usual over the San Joaquin Valley.

One Lindsay orange grower reports 7000 boxes of packed oranges from ten acres. This is not by any means the average for that section, however.

Construction work of extensions of the Turlock irrigation system is proceeding finely and much cleaning and improving of old canals is being done.

Hanford alfalfa growers have been slow in extending plantings this season owing to the drouth during the earlier part of the season.

Tulare county board of supervisors and horticultural commission is still contending as to whether graft has existed in various features of county work.

The precipitation during the last storm at San Jose broke all records in the 24 hours ending at seven o'clock, January 14th, with a four-inch rainfall.

The California Fruit Growers Exchange of Sacramento hopes to have a marketing union of apple men of Watsonville to affiliate with that exchange.

What is said to be the greatest water suit ever commenced in Madera county ended last week in the nonsuiting of the big Miller and Lux estate in an action commenced to condemn the waters of the San Joaquin river.

It is reported that packers are buying raisins in large blocks and all they can secure at 3 cents. The Republican reports that over 3000 tons were purchased last week. One company has made freest offers to buy 1911 goods at 3½c.

Southern California

Irrigation District No. 8 of the Imperial Valley is now raising 700 acres of seed peas.

A gypsum or land plaster plant has been constructed at San Fernando, Los Angeles county.

The California Fruit Growers' Exchange is spending $70,000 in advertising California oranges.

It is reported that 5,000 cattle on Santa Rosa Island, off Ventura county, are suffering because of the drouth.

Prominent Riversiders met last week and took steps to favor the proposition for appropriations in support of district fairs.

Mass meetings are the order of the day in the Imperial Valley. The burning question is reclamation control or irrigation district control of the water systems of that valley.

Contractors working under government direction are pushing the work on the great levees of the Colorado river. The effort is to secure control before the midsummer floods.

A member of the Tri-Counties Reforestation Committee presented a paper at its recent convention advocating individual ownership of small tracts of forest as a solution of the watershed protection question.

The latest in orange packing house equipment is at Redlands where a "tagging" machine is being used. The machine quickly pastes a little sticker attractively, calling attention to the quality of the fruit, on each orange packed.

The Yucaipa Land Company has a contract for fourteen miles of water pipe to conduct water to its lands. It is expected that this spring will see the planting of enough trees to make at least 1000 acres of apple orchards in the valley.

The railroads have adopted a new order for the protection of shipments of citrus fruits, in effect that "all packages containing citrus fruit must be reinforced by a metal strip passing over the top thereof and nailed to the sides of center piece." It will be put in effect March 1.

San Dimas and Glendora residents are much concerned over the proposed establishing of a factory and storage warehouse for giant powder by the Giant Powder Works, now located at San Francisco. The plan contemplates the storage of 100,000 pounds of giant powder in that section.

The Coast

The Farmers Union at Walla Walla, Washington, estimates that less than half the grain in that county has been sold.

Klickitat county wheat fields are covered with several inches of snow, and a promise of a big crop of fall wheat is made.

Oregon enthusiasts claimed that the exhibit at the recent wool growers convention shows Oregon to be the best sheep country on earth.

The Colville Indian Reservation north of Spokane, Wash., is now open to settlement. Over a million acres of lands are thrown open.

The president of the State Horticultural Society of Oregon predicts that the Pacific Northwest will soon be producing 100,000 cars of apples.

Lewis county fruit growers met in Chehalis, Washington, on January 9, and formed the Southwestern Fruit Growers Association, Incorporated.

Arrangements are being made for the formal dedication of the Roosevelt Dam in Salt River, Arizona, either in February or March. The dam has been in operation for some time.

Fruit growers at Cambridge, Idaho, are devoting the winter evenings to discussion of the question, "Resolved, That Spitzenberg is right and that Spitzenburg is wrong."

The Oregon State Agricultural College at Corvallis is planning to give much more attention to college extension work; in other words, will carry the college to the people.

The farmers of Utah are making a strenuous fight for better prices on sugar beets. Organizations are being formed over the state. The factories maintain they are paying highest possible price.

Farmers near Weston, Oregon, who have been working for a government reclamation project, are tired of the delay and are taking steps to secure control of the water and funds for conducting it to the land.

The Oregon State Conservation Commission and others who would see the forests preserved, have prepared a bill for presentation to the state legislature which provides for protection of life and property from forests fires.

The Washington State Dairy Association, at its recent meeting at Lyndon, resolved in favor of "compulsory testing of dairy cattle and requirement of certification of tuberculosis tests for all dairy animals, except for purposes of immediate slaughter."

CONTAGIOUS ABORTION.

Many terms are used in discussing this trouble such as "slinking," "casting," "losing," "aborting," etc., the idea being conveyed that the young is cast out of the womb before it is fully developed and capable of separate existence.

Causes.

Abortion may be brought about in many ways. The principal causes probably are injuries to the mother from fighting, falling, kicks from other animals, drinking excessively of very cold water, exposure to severe or sudden changes in the weather, and the eating of spoiled, frozen or moldy foods, especially wheat or rye which contain ergot or smut. Improper hygienic surroundings also contribute, especially in stabling, breeding too young, inbreeding, and severe constitutional diseases. The death of the foetus itself is at times responsible.

When any of the accidental or explainable causes cannot be assigned to the case, contagious abortion is always to be suspected, for it is common in this state and easily spread from one animal to another. The failure of many mares and cows to breed may often be attributed to this trouble. The diseased animals are often able to infect those with which they associate, so it is readily seen that the immediate loss of the young animal is not the only loss sustained by a herd in which this disease may get a foothold. It frequently results in many months of sterility or possible loss of increase completely, as well as infection of new herds of animals replacing the old herd.

There can be no doubt of the fact that the disease is of germ origin, or infectious, as we more properly say. The fact that it spreads rapidly from one animal to another, and that experimentally it can be produced by the introduction of the discharge of an affected animal into the vagina of a pregnant animal, both conclusively prove this point.

The germs of the disease are found in the vagina and uterus of affected animals and are passed out with the discharge from these organs, therefore the membranes and discharges from a case of abortion should always be buried, burned or thoroughly covered with strong and efficient disinfectant.

This is one disease where it is obvious that prevention is worth vastly more than an attempt to cure, mainly because the trouble is as a rule not suspected to be present until it has occurred, therefore treatment is directed to those animals supposed or known to be affected, and the known exposed ones, applying those sanitary measures necessary to check its spread.

Considerable experimental work has been done in attempting to control the disease and various methods have been more or less successful in herds that were affected in a mild form. This station carried on a series of experiments by using locally, at various periods of time, capsules filled with icthyol and other disinfectants. Also giving salol internally. None of these methods proved as satisfactory in controlling the disease as the following:

Treatment.

Burn the foetus and membranes, together with all litter soiled with the fluids. Clean out the barn and burn the refuse. Whitewash the walls with spray or brush with a solution of corrosive sublimate, one ounce in eight gallons of water and lime. Repeat this process often and get all drains and floors well covered with the antiseptic fluids.

Separate aborting animals from those supposed not to be affected and keep them separate until they are entirely well. Wash off the tail and surrounding parts of all animals with a solution of creolin or phenol, two per cent in water, and irrigate the uterus with a 2 per cent solution of phenol in water kept thoroughly mixed. This is best performed by using a funnel and hose five or six feet long, inserting one end in the uterus, and pouring the antiseptic solution into the funnel, allowing it to run in gradually.

Many animals, even those which have persistently refused to breed, can be made profitable breeding aniamls again by the following method:

Boil and cool one quart of soft water. Add to this five drams of pure crystals of phenol. Keep this solution in a well corked, sterilized bottle, shaking it vigorously each time before using any of it. Get a hypodermic syringe, similar to those used in vaccinating for blackleg, and treat the affected animals by injecting under the skin about one to one and one-half ounces of this solution, putting one to two drams at different points of the body. Repeat every seven to ten days till about six treatments are given. After about two treatments increase the dose to all the animal will stand. To do this give one or two extra syringes full and wait a little while, all the time watching the eyes. If the pupil dilates, enough has been given. An overdose makes some animals quite sleepy, or they stagger a little, but these symptoms are not dangerous and soon wear off. To give all the animal will stand without staggering is good practice after about the second treatment.

If faithfully followed, the above directions should rid any herd of contagious abortion in a short time and it will probably check the tendency. To herds suspected of possible trouble, thoroughly mix one pound of phenol with five pounds of salt, and give to each animal a tablespoonful of the mixture in a bran mash every other day for a week. This will probably prevent the threatened abortion.

Bulls which have served aborting cows can spread the disease, so the sheath should be irrigated before and after each service, the same as was directed for the irrigation of the vagina in the female. The bulls should also be given the hypodermic treatment and should be isolated and kept from associating with herds wherein the disease has not been found.

Some cows and mares have repeatedly failed to conceive after service and this condition is often due to the acidity of the fluids of the uterus which prevents conception. The dif-

ficulty is best overcome by soaking a cake of ordinary yeast in about a quart of lukewarm water over night, keeping it at about body temperature all the time; this solution should be strained through a clean muslin cloth and injected into the vagina of an animal a few hours before service. It neutralizes the acids and overcomes the trouble in many cases.—K. W. Stouder, Kansas Experiment Station.

BREEDING UP A DAIRY HERD.

"If I had that bull back I would not take $1000 for him. He got big and hard to handle, and I let him go to a butcher for $40, but everyone of his heifers turned out to be a great milker, and had I had the sense to have kept him and line bred his stock, I would have had a record-breaking dairy, as I can now well see." This man's experience is no different from that of scores of others who follow the custom of keeping a sire only one or two years at the most and then getting something else with almost a sure possibility that the good influence of the first sire is halved up by the second, which means in reality the loss of all ground previously gained.

The prevailing custom of a community is a hard thing to overcome with a new practice, especially in the breeding of dairy cows; notably where, for two or more generations, it had been the practice or custom to ignore breed lines in securing even the heifers to make the dairy members good, and all the more so when sires were changed every year, and if a sire of dairy breeding was procured he went the next year the same as the brindle one had the year before, and he was in turn followed by a yellow-and-white sire of unknown ancestry because he was cheap in price, and his calves were to be sold for "bobs," anyway.

Such a plan never increases the value of stock beyond the range of canners' prices, and now that there is an awakening to the fact that dairy stock needs the prepotency of a breed ancestry behind it the gravest danger threatens that the old custom will be kept in partial practice at least and the history of our friend's sire will be repeated over and over and a retrograde condition will result and even the grades of merit will in turn be graded or degraded, by the use of sires of unknown quality.

Often the remark is made: "I cannot afford to have high-bred stock. I must raise grades." Then all the more essential is it that only sires of the best are used and kept as long as possible. With a sire of strong blood lines, and developed vitality, there will be no necessity with grade cows of an outcross for three generations at least, and the third generation will be 87½ per cent of the intensified and reinforced blood of the sire, and to all practical purposes the equals of pure-bred stock and at no more cost than the common stock he had supposed he must always possess. The history of all high-class breeding and best records is where little latitude has been given to the introduction of new sires, keeping to the line even of one family of a breed and not getting scared in breeding now and then heifers back to their own sire to double the prepotency of the milking function.

In this vicinity there is a great demand for high grades of a certain breed of dairy stock, and a month-old heifer calf of a grade cow, if it had a thoroughbred sire from the same family breed, brings the price of a horse; but the calf of a grade cow, mated with an unknown bred grade, brings veal prices and no more. In this intensifying the blood of a grade by the influence of a pure-bred lies the whole success of the uplift of our dairy stock from the common level of the past; and if the customs of the past are to prevail, with frequent changes of sires, and sires of unknown quality, and mixtures of blood, the last condition of this dairying will be as unsatisfactory as the first.

For the dairyman needs only the one thought and purpose in mind, that of a dairy breed and type of the breed, and to keep in that line with sires of strong dairy prepotency and of the same breed as are the cows. Dual purpose is a stumbling block to him. What does he want of a beef steer or beef in any paying form, when a 20-months-old heifer, well-bred, will today, in sight of my house buy three steers of equal age. And why should this man want to mix dairy breeds, when he gains nothing in production and decreases the value of the "mix" 50 per cent.—John Gould in Tribune-Farmer.

COUGH IN PIGS.

There are a variety of causes for cough in pigs. In the summer-time the most common cause is worms, either of the intestines or of the lungs; but in the winter time cough is often due, as in man, to a cold affecting the throat or lungs.

If the pigs are drawn up in their bellies, seem to be affected with indigestion, and especially if any traces of worms are found in their droppings, the cause of the cough is probably worms, and we would advise one of the following treatments:

For each one hundred pound pig mix one teaspoonful of turpentine with milk. Give this to the pigs in the morning before they have had anything to eat. Repeat the dose for three days in succession.

The Iowa Experiment Station recommends the following treatment as effective: Dissolve one dram of finely powdered iron sulphate for each one hundred pounds of hog flesh, in warm water, and thoroughly mix with the slop which is fed in the morning, every other morning for a week. If the case is a bad one, continue the dose for two weeks. And if the pigs still continue to do poorly, repeat the treatment in six weeks or a couple of months.

It is always a good plan to keep a mixture of salt, charcoal, ashes, lime and iron sulphate before growing pigs.

If the trouble seems to be due to an affection of the throat or lungs rather than to worms, we advise the following treatment: First, put the affected hogs in warm, clean, comfortable quarters—pens which are not in the least dusty. Feed the pigs a light, sloppy ration. Steam the badly affected animals with a solution made by adding one part of turpentine to two hundred parts of boiling water, for fifteen minutes twice daily. This is said to be effective. The steaming solution held under the pig's snout is supposed to help restore the air passages to a normal condition. It is a good plan to disinfect the pens and sleeping quarters with carbolic acid or some other good disinfectant.—Wallace's Farmer.

Citrus and Tropical Fruits

FERTILIZING VETCHES AND BEANS.

By R. M. Morris.

As the result of many experiments the Citrus Experiment Station at Riverside places the vetch at the head of the cover crop list. The vetch is an annual legume. The stems are weak and do not support the plant. The leaves are compound, having six or ten leaflets, and are terminated by little tendrils which attach themselves to whatever they can find for support. While the plant has grown as much as 8 to 10 feet in length, ordinarily it does not exceed 3 or 4 feet, and is usually shorter. It has been known to make some very heavy yields. When sown alone, to be turned under, about 60 pounds of seed are used per acre. One of the advantages in cover crops is that the roots penetrate to depths which it is impractical to reach with machinery. This means that by and by these roots decay and are not only converted into humus, which makes a home for bacteria, but allows a freer penetration of air and water.

The vetch is a heavy feeder on the mineral elements, potash and phosphoric acid. When the crop is plowed under the potassium and the phosphorus which it contains are returned to the soil, and these elements are then probably as available as they were before. But undoubtedly much of this fertility is taken up by the trees in the groves where these crops are grown.

When vetch is to be cut for hay, it does better when sown with rye or wheat. The latter is preferable since it is slower in starting than rye, and therefore, not so liable to smother out the vetch. This mixture makes ideal hay and will yield about six tons green hay per acre.

When the vetch is thus utilized for hay and is taken from the field, a large amount of the mineral elements of the soil are removed. It can thus be seen that whether sown for a cover crop in a citrus grove or for hay, it should be liberally supplied with potash and phosphoric acid. A mixture of 250 pounds of 17 per cent superphosphate and 150 pounds sulphate of potash should be drilled in at the time the vetch is sown. This will not only insure a perfect stand and a heavy growth, but it will cause it to be more helpful to the trees, if grown in a grove, and prevent the ground from becoming improverished, if grown for hay.

There is a tremendous acreage of beans grown in Orange, Ventura and other counties of Southern California that are unfertilized. Since the roots are left in the ground, and in some instances the tops returned, it is said that in some places the yield of beans per acre has increased rather than dimished during the past few years. But if there are such instances, it will also be noted that a careful preparation of the seed bed has been made and most thorough cultivation practiced. Beans belong to the family of legumes and have that mysterious power of attracting atmospheric nitrogen; but like vetch, clover and all other leguminous crops, they are heavy feedrs on the mineral elements, phosphoric acid and potash. Therefore, a liberal supply of these elements must be present either naturally or applied, if large crops of marketable beans are to be secured. As a hint to the grower, who is going to try commercial plant food, I would state that nothing but high-grade materials should be used. While a nitrogen gathering crop, if the beans are to be grown on clay or sandy land it will be well to supply some nitrogen, say 100 pounds of nitrate of soda or dried blood per acre. But on most soils, the elements mostly needed will be potash and superphosphate. At least 125 pounds actual potash and 200 pounds available phosphoric acid should be used per acre. Since the ground is usually prepared early, there will be an advantage in applying the fertilizers from two to three weeks before the beans are sown. The plant food should be applied broadcast by hand or sown with a drill and worked into the soil by using a light harrow.

THE USE OF FERTILIZER UPON CITRUS FRUITS.

By George Wright.

It is not always good business practice to wait for "signs of deficiencies in the soil" before making judicious use of commercial plant food. The entire question of the advisability of the use of fertilizers is a relative one, and may be reduced to a determination as to whether or not, by their proper use, there can be obtained an increase of crop sufficient to allow something of a profit after meeting the extra cost of fertilizer and labor. This is a matter which each grower can only determine for himself.

No horticultural crop has given more satisfactory returns from fertilization than the orange. The experience both in California and in Florida has been that judicious use of commercial plant food has had a wonderful effect in starting active vegetation and increasing production.

With the orange, as with other fruit, with its attendant open culture, there is constantly being withdrawn from the soil large quantities of plant food. Here we have a crop that is entirely sold off the land, entailing a constant drain upon the soil fertility, hence manuring soon is forced upon the attention of the grower and becomes one of the most important considerations in the extensive culture of citrus fruits. Once the soil fertility is exhausted, all operations are of little avail, if it be not replaced. That this may be more rationally done, it is necessary to take into account, besides the nature of the soil, the composition of the plant and the condition of vegetation. Knowing these, we should be able to judge with a fair measure of accuracy, what elements are likely to be needed and in approximately what proportion.

It is self-evident that attention should first be directed to supplying soil deficiencies, when these are known to exist, and then to returning to the soil such an amount as may have been withdrawn by the crop produced.

Since the first is a matter which is entirely dependent upon the local conditions and the character of the soil, no general treatment can be given. The second, however, is inseparable from the crop.

Figured upon the average composition of California oranges, and estimating the crop per acre at 20,000 pounds of fruit, there is removed from the soil annually per acre:

Nitrogen ..... 36.8 lbs.

STAR PORTABLE DRILLING MACHINES

More Profitable Wells

Can be drilled with the right machine. In buying a Drilling Machine, the first vital point is to be sure it will yield you the greatest possible service—and hence the greatest possible profits. You *must* know.

Star Portable Drilling Machines

have stood the test for years in comparisou with all makes, and the very fact that fully 95% of all Portable Machines now at work in the Oil Fields are Star Machines is all the proof necessary as to their superiority for all kinds of Well Drilling.

Drilling Machines,--Engines,--Cordage,--Etc.

SILAS TOMS & SON,

PASADENA, CAL.

Phosphoric acid	10.6 lbs.
Potash	42.3 lbs.
Lime	19.7 lbs.

These figures do not express the total amount of plant food withdrawn from the soil, for no account is taken of that used by the tree itself in building its tissues. It is a very definite expression, however, of the amount withdrawn by the fruit and shipped away to some distant point never to be returned except by the use of fertilizer. As to the amount removed by the parts of the tree other than the fruit, analysis shows as follows:

In 100 parts:

	Nit.	Ph. Acid	Pot.	Lime
Leaves	.70	.10	.32	.77
Trunk, br'ch	.70	.43	.58	.80

We may fairly assume, perhaps, although it has not been demonstrated, that the natural unlocking of plant food from its less available sources will, in most cases, supply the needs so far as wood and leaf is concerned, in such quantity as to sustain life, but probably not for many years in sufficient amount to impart a vigorous growth and induce liberal fruiting with high-class fruit that will make for profit in citrus culture. Attention, then, must be given to the restoring of the annual draught and placing the tree under such conditions of liberal food supply as to place it at its highest efficiency for healthy growth and abundant fruiting.

In referring to the table preceding, showing the plant food removed by the orange, it will be noted that the proportion of nitrogen, phosphoric acid and potash stand about as follows: Nitrogen: 4; Phosphoric acid: 1; Potash: 4, and were it sufficient to supply the exact balance for the fruit only, that proportion might serve as a basis for a fertilizer mixture; but there are certain soil conditions to be taken account of which result in mechanical and chemical losses. For this reason under ordinary conditions, the proportions of phosphoric acid and potash have to be somewhat increased. A formula which has given good results is the proportion of:

Nitrogen	4 per cent
Available phosphoric acid	8 per cent
Potash	4 per cent

In connection with citrus growing, it is of particular interest to keep in mind the functions of potash, especially as they are so vital to the quality of this class of fruits.

Potash, as a plant food, seems to influence especially the development of starch and sugar, the development of the woody parts of the plant and the pulp of the fruit, thus filling out the framework built by the nitrogenous ingredients. The flavor and color of fruits is also accredited to potash to a greater or less extent. A lack of potash is said, by Webber, to cause, in the orange, "an excessive growth of weak; immature wood, which does not harden up as winter approaches and is liable to be injured by frost," in localities where such occur. It is also associated with the chemical changes which takes place in the translocation of the starch from cell to cell. Webber says: "Its greatest importance is in connection with protein formation, in which it is apparently indispensable."

The lack of potash is often first evident from a decided lack in growth even though the foliage maintains its green color and there appears to be no apparent cause for the trouble. The potash of fertilizers is almost exclusively from either sulphate or the muriate of potash, either of which carries about 50 per cent of actual potash entirely soluble in water, hence immediately available.

KIRKMAN NURSERIES

TREES THAT GROW AND BEAR TRUE TO NAME

We are wholesale growers of deciduous and citrus fruit trees, grape vines and eucalyptus trees.

Our stock this season includes 650,000 deciduous fruit trees alone. A large lot of these are on Eastern seedling root, which has proven to be almost proof against root knot.

Get the best stock available and at the most reasonable cost from a man who selects the buds and scions of the best strains.

Deliveries made from our sales yards at Fresno, Madera, Merced, Turlock, Banning and Chico.

Tomato "Tennyson"

This grand variety is now offered for the first time, and we honestly believe will fill a long-felt want for an ideal tomato for private homes, market gardeners, etc., that grow tomatoes for profit and pleasure.

"Tennyson" is 4 to 6 weeks earlier than any other sort grown on this west coast.
"Tennyson" will be ready for the table three months after planting, and will have 100 or more ripe tomatoes on each plant.
"Tennyson" delights in an abundance of water, and plenty of rich stable manure, the more you feed it the better it will fruit; no waste growth; the fruit sets on the first flower.
"Tennyson" has a lovely flavor, making it quantity and quality combined.
"Tennyson" is of a dwarf habit, its growth is spreading, every branch bearing its beautiful fruit.

Seed per pkt. 25c.

Plants ready March 1st, 15c each; 2 for 25c; 6 for 75c; 12 for $1. (By Express).

Deciduous Bush-Tree Fruits

RECOMMENDED FRUIT TREES.

At the request of Tulare Grange former Horticultural Commissioner P. D. Fowler suggested the following desirable fruits for plants in that section of San Joaquin valley. It is suggestive and valuable in any section of the state.

Peaches, Free Stone.

Sneed, May 25.
Briggs, Red May, June 15.
Alexander, June 15.
Admiral Dewey, June 15.
Early Imperial, last of June.
Hale's Early, early July.
Foster, middle of July.
Elberta, last of July.
Muir, last of July.
Lovell, August 15.
Morris White, August 10.
Salway, middle of September.
Ward's Late Free, Oct. 1st.
Opulent White, a cross between Muir and White Nectarine, Aug. 1st.

Peaches, Cling Stones.

Yellow St. John, late June.
Tuscan Cling, yellow, middle July.
Sellers Orange Cling, yellow, middle August.
Phillips Cling, yellow, early in September.
Levy Late, yellow, middle September.
Persian Cling, middle of August.
McKevitt's Cling, last of August.
Heath Cling, middle of September.
Georges Late Cling, late in September.

Apples.

Red June, June 1, red.
Red Astrachan, June 15th, red.
White Astrachan, July 1, white.
Duchess of Oldenburg, July 15, yellow streaked with red.
Early Harvest, July 1, light straw color.
Red Beitigheimer, August 15.
Swaar, November 15, yellow with brown streaks.
Wine Sap, November 1, red.
Ben Davis, November 1, red.
White Winter Pearmain, November 15, white.
Lawver, December 1, red.

Pears.

Doyenne d'Ete, small, yellow, shaded with red, July 1st.
Beurre Giffard, medium size, greenish yellow, July 15.
Bartlett, August 15.
Winter Bartlett, November 1.
Winter Nelis, December 1.

Plums.

Climax, middle of January, purple.
Prunis Simoni, early July, purple.
Bary's Green Gage, August 15, greenish yeilow.
Satsuma, August 1, purple, flesh dark red.
Shropshire Damson, Sept. 15, blue.

Prunes.

Tragedy, dark purple, early July.
Robe de Sargent, black, August 20.
French, black, September 10.
Hungarian, September 15.

Apricot.

Pringle, May 15, small.
Royal, June 1, medium, good canning and drying.
Blenheim, June 15, medium, good canning and drying.
Hemskirke late June, large, good canning and drying.
Tilton, middle June, large, good canning and drying.

Nectarines.

New White, large, early, July.
Stanwick, large, August 15, greenish white.

Quinces.

Pineapple late August.
Smyrna, late September.

Almonds.

Drake's Late August.
Texas Prolific, August 15.

Walnuts.

Franquette, grafted on California Black root.
Mayette, grafted on California Black root.

Figs.

Calimyrna, August to October.
Mission, June to August.
San Pedro, black, early in August.

Grapes.

Thompson Seedless, white, August.
Malaga, white, August.
Muscat, white, September.
Rose of Peru, black, October.
Purple Damascus, black, September.
Black Cornichon, black, October.
Sabal Kanski, red, September.
Flame Tokay, red, September.
Emperor, red, November.

Blackberry.

Mammoth Blackberry, early June.
Loganberry, May.

Strawberry.

Brandywine.

NO SURPLUS OF GOOD FRUIT.

It is an interesting fact that the great extension of fruit growing, in all parts of the country, has been attended, not by a decline in prices, but by a very considerable advance. The question whether or not the multiplication of orchards and berry patches will have the effect of producing a glut, so as to render profitless the labor and expenditures of the fruit grower, seems, then, very likely to meet a negative reply.

In the first place the demand for all the fruits of North America is worldwide. The world's appetite for them is insatiable; and as the facilities for distributing them are better systematized through intelligent co-operative arrangements between growers and transportation agencies, and selling agencies in the cities, it seems as though the problem is to be, not how to get rid of surpluses, but how to get enough of any kind of good fruit.

In years of great abundance in American apple orchards, good apples have sold in Mexico at 15 cents apiece. In London they have retailed at 25 cents apiece. Other fruits, capable of bearing transportation for long distances, have commanded proportionately high prices. Of course, these prices have been for choice fruit. In New York and Boston even 10 and 15 cents apiece has been readily obtainable for choice apples.

Such exceptional figures as those above quoted are not, however, necessary as a basis for profitable fruit growing. The moderate prices paid by the mass of American consumers are sufficiently high for that; as in thousands of homes, our people are learning to prefer fruit, at such moderate prices, to many another article of food which they have heretofore demanded.

The improvement of canning processes and the cheapening of apparatus has also its effect in insuring a market for fruits. Fruit farmers are not now depending on "canneries." Recent inventions enable them to do the canning themselves.

It would seem, then, that the grower

Power Sprayer

For

LLOYD R. TAYLOR, Modesto, Cal.

need only see to it that his fruit is of good quality, attractively put up and intelligently marketed to be certain of a reasonable reward. But the day when neglected orchards and bushes could be depended on to produce salable crops has passed. The grower of today must be equipped by study for battling with insect pests; must be insistent in cultivation and in the use of the sprayer; and must, in short, give as close attention to his trees as the stockman does to his cattle, the doctor to his patients, or the merchant to keeping his stock of goods fresh and in salable condition.—Market Growers' Journal.

WALNUTS IN SANTA BARBARA COUNTY.

From the report of Prof. C. W. Beers, horticultural commissioner of Santa Barbara county, we note the following on the walnut question:

"Three days of this month were devoted to field work in a study of the walnut industry in connection with Prof. E. R. Lake from the agricultural department at Washington, who was making an exhaustive study of the question as presented on the Pacific Coast.

"Professor Lake had worked his way down from Utah, Washington and Oregon, through the northern part of California into this section. In our field he found the first positive standard type of nut of the Santa Barbara soft-shell variety. The type of tree, with its own type of nut, and its uniformity from Tecolote to Carpinteria, determined what should be considered the type for the Santa Barbara soft-shell walnut from the government standpoint.

"It was found that in our own section there are three distinct types of nuts now being grown and being selected as types for future planting, namely: the Santa Barbara soft-shell, the Khaghazi type and the Pecan type, each nut being distinct in its own field and each appealing to different demands and making its own market.

"A very general disposition to seek grafted trees for new plantings became evident. Each grower is disposed to make careful selection of type nuts for planting, only the very best of the seedlings to be preserved, and then make a careful selection of scions from his own most satisfactory trees for budding onto these selected seedlings. Scion selections to be made with three prominent ideas: selecting from trees showing least disposition to bacterial attacks, those giving the best type of nut and those showing large productiveness. In this manner it is believed a very high type of tree may be secured."

HE DIDN'T HAVE IT.

Miss Merrill, a teacher in a grade school, had trouble with Johnnie last week. Johnnie had trouble doing his work, and the authorities finally discovered that his sight was defective. Miss Merrill told Johnnie, and sent him home with a note to his mother. He gazed at the note in horror, then at the teacher, and burst into tears. The note read:

"Johnnie has astigmatism. Do not let him return to school until he has been attended to."

Miss Merrill understood his grief better when she received a note from his mother. She read: "I don't know what he has done, but I licked him for it. I can't find it on him, and he says he ain't got it, now you better lick him and see if you can find it."—Chicago Record-Herald.

SWIFT'S
ARSENATE OF LEAD

For

Codling Moth, Canker Worm, Bud Moth, Pear, and Cherry Slug, and all leafeating pests.

Perfect Protection

One orchardist writes that after using Swift's Arsenate of Lead, he found but sixty-four apples affected by the codling moth out of 1141 boxes, or 1-200 of 1 per cent.

Does not scorch or burn no matter how strong it is used.

In 1 lb., 5 lb., 10 lb., 20 lb., 50 lb., and 100 lb. packages.

Questions and Answers

THE EDITOR AND STAFF

Questions to be answered in this department should be received at this office one week before reply is expected. Write plainly on one side of the paper and sign full name and address. Unsigned communications receive no attention.

Leghorns.

What breed of chickens will do best in this section? It is sometimes as cold as 16 degrees above zero, though seldom below 20 degrees. Will White Leghorns live in a climate like this? Are they any more delicate than other breeds?—Subscriber, Laytonville.

There can be nothing in your temperature to interfere with White Leghorns. They are not so popular in the East as they are in California, and perhaps the zero weather of that section would interfere with their best development, but we believe anywhere in this state climatic conditions would not be unfavorable.

Agricultural Books.

In your interesting article on horticultural training for boys you speak of books of value and of state and national reports. Where may these be secured?

The Cultivator can secure from publishers, at their list price, books of value, list of which is now being made up by the business office and will be ready in a short time. Bulletins of the state agricultural experiment station may be had by addressing Prof. E. J. Wickson, Director, Berkeley, Cal. Reports of the state horticultural commission may be secured by writing to J. W. Jeffrey, State Horticultural Commissioner, Sacramento, Cal. Write to Department of Agriculture, Washington, D. C., for bulletins of the Department of Agriculture. These latter are so extended in their scope that it is best to be specific along the particular line of information desired. The annual year book may be obtained by writing to your congressman or senator at Washington.

Aylesbury Ducks.

Where can one secure pure-bred Aylesbury ducks or eggs?—Subscriber, Santa Rosa.

We think later Cultivators will contain announcements of Aylesbury breeders.

Planting Orange Seed.

What time of the year should one plant orange seed?—Subscriber, Buena Park.

The early spring months, depending upon the season. The time ranges from March to May. If your soil is cold and there is danger of the seed decaying in the ground, hold until it warms up later.

Removing Fruit.

Should all of the oranges be cut off of a young Valencia tree which will be three years old this coming March, or only a part of them, or any? I notice that among my trees the ones which have the most fruit are invariably the smaller ones. They are perfectly healthy to all appearances, but something must be the matter to make them go to fruit when trees of the same age but much larger are putting on no fruit at all.—Subscriber, Tustin.

The fact that your trees are small and bearing indicates lack of strongest vitality. An orange tree will invariably begin to bear when out of condition. We have seen trees which were bearing a fair crop of half-grown fruit gophered and immediately they began to bloom and set a second crop. In your case, it may be simply a gravel pocket or some soil condition which has put the tree slightly out of vigor. We would investigate and if necessary add fertility. As to removing the fruit; trees of that age may be permitted, if fairly thrifty, to carry a little, but tree growth is of greater value.

Bees in Building.

I have been bothered for over a year with a swarm of bees behind the rustic of my house. It is a very difficult place to get at them owing to the fact of there being several plumbing pipes entering at the same place. In fact, it was through this means that they were enabled to gain ingress. What I desire to know is how to get rid of them without tearing out that side of the house?—Subscriber, Tustin.

This is a very perplexing question to answer for only studying immediate conditions will be of any help. Plugging the entrance is usually futile, for the busy little fellows generally find another. If possible to remove the rustic, clear away all of the comb and capture the queen. This will probably result in driving them away. It is barely possible that by making a hole and inserting a ball of cotton or other absorbent thoroughly saturated with bichloride of mercury, you could kill the whole swarm.

Cutting Eucalypts.

What time of year is it best to cut eucalypts, to make sure of getting second growth? At what height from the ground? Trees are now six to twenty inches in diameter. Varieties are blue gum, red and tereticornis.—Subscriber, Selma.

We believe the best time is when the tree is as nearly dormant as possible. We have heard timber cutters say that they did not believe there was any season at which one may be perfectly sure of all the trees living, but we have never seen trees cut in the fall, say from Thanksgiving to Christmas, that did not sprout nicely the following spring. If cut in the spring, after the flow of sap has started, there seems to be greater danger of the sap souring and the stump beginning to rot. We do not think the height from the ground is material.

Peanuts on Overflowed Land.

Have just purchased 160 acres, and wish general information as to handling. It is southeast of Wheatland two and a half miles, and a couple of years since a break in the levee admitted the river and lots of sand was deposited on some of the land. Will this produce good peanuts, and what kind is best? Is it necessary to cover blossoms? Also, will sweet potatoes do well in this river sand? Have silo now empty, but anticipate filling it next summer. Will plant oats, barley and wheat; also early potatoes. Will beans do well on this soil?—Subscriber, Sheridan, Placer County.

It is impossible to give advice regarding so general a matter. The depth of the sand over the good soil, also the coarseness of the sand, are factors which will have to be determined by examination. We have seen where breaks in levees have admitted strong currents of water, and coarse, sharp sand has been thrown in banks several feet in depth. Of course, such land was entirely ruined. Again, where the water has been more quiet, a fine silt has been deposited to the depth of an inch or two, and the land has been really benefited. If the sand on this land is not too deep for the roots to reach through it into the soil below, it may prove very beneficial.

Peanuts require sandy soil, and do not need to have blossoms covered, but we would refer our subscriber to Cultivator of April 23, 1908, the principal article of this issue being given over to culture of the peanut. Regarding other crops to be grown, the best information can be had from immediate neighbors. What has succeeded well in soils of a similar nature is the crop to plant. Our impression from the meager information given is that there are great possibilities on such a ranch.

Veterinary

Answers in this column by Dr. Fred G. Matthews, are without charge. For immediate mail answer remit $1.00. In writing questions give full symptoms or particulars of injury of animal.

Abnormal Lactation.

A mare eight months gone with foal is leaking milk freely. She is very fat, fed liberally on alfalfa, and allowed to run in a small lot. Will this kill the colt?—Subscriber, Dos Palos.

While this condition will not destroy the foal, it is not advisable to permit it to continue. Feed sparingly and exercise regularly at light work till the flesh is reduced to working order. This will be better for both mare and foal.—F. G. M.

Hollow-tail in Cows.

Is there any such disease as "hollow-tail" in cows?—G. R. G.

No. The practice of cutting out a segment of the bones of the tail is painful and if a weak cow under this cruel treatment exerts herself to get upon her feet the method deserves no more credit than administering a severe beating with a club which would accomplish the same end.—F. G. M.

Constipation.

Will mustard relieve constipation in cows, and what is the dose?—Subscriber, Dos Palos.

Mustard may be administered to cows in doses of one ounce or less. It stimulates motion and secretion in the stomach proper, but its action on the intestines is uncertain, hence it is doubtful if it could be relied upon as a laxative. Epsom salts in one-pound doses as a drench is preferable.—F. G. M.

Teat Duct Closed.

A heifer has lumps in the udder, which seem to work down into the teat while milking. The flow of milk stops after the milk has been squeezed out 6 or 7 times.—Subscriber, Holtville.

A membrane spans the space at the base of the teat. The opening in this membrane is too small to permit the milk to flow freely into the teat, therefore when the teat is emptied some time is required for it to fill again. The opening in the membrane may be enlarged by the use of a slender knife passed up the teat, but a skilled surgeon should be employed to do the operating.—F. G. M.

Injured Udder.

The udder of a cow has been injured by some object penetrating one quarter above the base of one teat. Matter collects in the part and escapes through the wound and also from the point of the teat. Can this teat be saved so it will give milk again?—E. S. N.

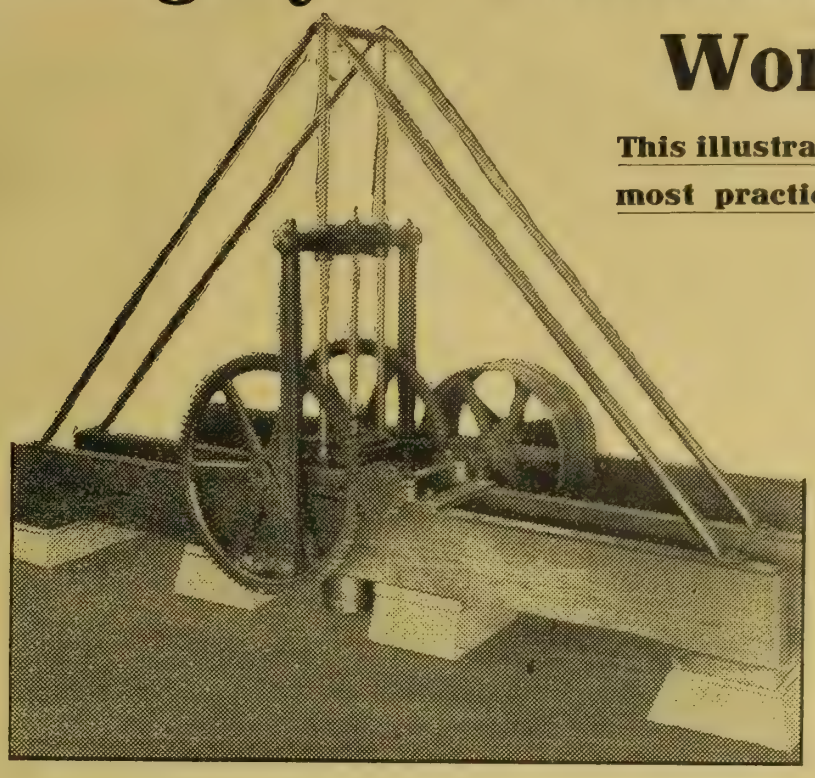
It is doubtful if the quarter will ever yield healthy milk again. Even if cured it is liable to inflame at the next period of lactation. Inject peroxide of hydrogen, diluted with an equal amount of water, into the opening of the teat and also into the wound, using a syringe the nozzle of which can be introduced into the openings. Press this out and repeat till the cavity is cleared of all matter.—F. G. M.

Indigestion.

A horse, 17 years old, has had three spells of colic during the past three months. He paws, rolls and bloats considerably. Is fed barley hay and ground barley and twice a day given condition powders.—Subscriber, Creston.

Some horses at the age mentioned are subject to spells of colic which implies indigestion. Discontinue the condition powders and give one pound of epsom salts dissolved in a quart of water as a drench. Allow this 38 hours to act, and follow with one tablespoonful of hyposulphide of soda in the feed, twice daily for about one week.

Gregory's Combination Working Head



This illustration shows our latest and most practical deep well Pump Head.

This head is the production of years of hard work and careful study and is made to meet the demands of the California rancher.

Tight and loose pulley for belt. Heavy gearing, strong, durable. Nothing to remove in order to pull the rods.

Nothing to get out of repair. Any length of stroke from 10 to 24 inch.

ABSOLUTELY NO VIBRATION.

Home Grounds Beautiful

THE JUJUBE TREE.

One of the most ancient of cultivated fruits, highly esteemed in the Orient, but little known in America, is the jujube or Chinese date plum produced by several species of small trees of the genus Zizyphus, natives of eastern Asia and Palestine, south to India and even Ceylon. Of these Zizyphus sativa or vulgaris stands first in importance, as it is by far the hardiest, being naturalized in southern Europe and growing well, though not fruiting freely, in this country as far north as Philadelphia. On the Pacific Coast it is hardy at ordinary elevations up to the Oregon line, and probably can be fruited in any locality not subject to sharp winter frosts. It is sparingly planted in the Gulf States and California, but deserves consideration as a commercial crop where conditions favor its full development. The drupe-like fruits are borne in the greatest profusion on short deciduous, leafy branches over the whole tree, and range in size according to variety from small cherries up to that of good-sized plums. The whitish flowers are not conspicuous but are freely produced on the new growth throughout the early summer months, the fruits ripening near the close of the year and turning various shades of brown as maturing advances. Trees are generally of graceful, upright growth, the aspect in late fall strangely simulating that of a young eastern locust or Pseudacacia covered with chocolate plums in place of seed pods—a resemblance further enhanced by the numerous sharp spines found on most jujubes and the apparently pinnate character of the foliage. The fruits are scarcely edible until they shrivel, which usually occurs in dry climates before dropping. The flavor is then to be compared with rather sweet and tender dried apples, or rarely with that of certain edible hawthorn fruits, but there is great difference among varieties as regards sweetness, acidity and mucilaginous character of the flesh. Each fruit contains a single relatively large pit or stone-like seed, but in some of the prized Chinese sorts this is reduced to small proportions, and is even said to be lacking in certain choice varieties, not yet introduced to cultivation in this country.

The jujube fruit is scarcely known in commerce save in Oriental countries, where it is extensively used in the preparation of sweetmeats and confections in great diversity of forms, but what is termed jujube paste in Europe and America is said to be principally compounded of sugar, gelatine and gum arabic, with fruity flavorings. By suitable preparation the fruits can be made to yield a large proportion of well-flavored fruit pulp, suitable for high-class confections, conforming to the most stringent requirements of pure food legislation and would doubtless be in large demand were the home supply assured. Though of little utility for domestic use, jujubes have great possibilities as manufactured products. The Chinese "dates," largely imported by the Celestial residents of our cities, are crystallized jujubes, and are often little inferior either in size or quality to the best products of the true date palm, while in hardiness, general ease of culture and early productiveness, the jujube tree is greatly superior. It is not unusual for little plants to show blooms while still in the seed leaf. Trees commonly bear when four or five years old, and produce abundantly after the sixth year.

Jujubes are freely propagated by means of buds, grafts and cuttings of green or even hard wood. Like other long cultivated fruits, seedlings do not with certainty perpetuate the variety and propagation for orchard use should be made by some of the above methods from known worthy sorts. The agricultural explorers of the National Department of Agriculture are searching for the best jujubes grown in Northern China, and in due time really desirable varieties are likely to become available for extended trial.

Zizyphus Jujuba is less known in this country than Z. sativa, though a great favorite in the warmer portions of the Orient. The fruits are well-flavored, though often somewhat acid, and the tree is quite ornamental, with generally drooping branches. The young growth is covered with a brownish down. It probably can only be successfully grown in frost-free climates. There is also a native jujube, Z. Parryi, found in Southern California, but the fruits are so dry and mealy that they are regarded as of little account. There are several other species of limited horticultural value.—Rural New Yorker.

POTTING PLANTS.

On proper potting depends materially the success of not only house-plant culture but a good deal of greenhouse work. Potting is a general term applied to the first setting in a pot or the transfer from one size to another for providing additional rooting space. The requisites are pots of suitable size, materials for drainage and compost adapted to the wants of the plants operated on. Take a pot, place a large piece of broken potsherd over the hole in the bottom with its convex side downward, and on this add a layer of broken bricks or other porous substance, varying from half an inch to two inches in thickness, according to the size of the pot and the nature of the plant. On this place turfy or lumpy pieces of the soil or compost (not sifted, but reduced by the hand to the size of pigeon-eggs), adding enough so that the plant will stand with the top of its attached mass of earth just below the level of the rim of the new pot.

The plant should next be attended to by gently inverting its pot in the hand and giving the edge a gentle tap, so as to remove the soil in one mass without disturbing the roots. Holding the plant in this position, displace the drainage material which had before been used and gently disengage the tips of the roots around the sides; then set it firmly in the new pot and fill firmly between the old mass of soil and the sides with compost. Finish the surface off evenly with the base of the stem about level with the rim and the soil near the rim a quarter to half an inch below it according to the size of the pot. It is important that the soil should be sufficiently dry when used to bear compression without becoming adhesive. The proper time for repotting is when each plant has filled just the soil about it with roots and extracted the nourishment from it, without having been left till the soil is exhausted or the roots matted or tangled. Whenever this state is reached (except in mid-winter) repot at once.

When space is limited, this increase in the size of pots should not be too rapid, say two sizes at each shifting, although this will not secure the same rapid growth which results from the adoption of larger pots. Free-growing plants, such as geraniums, will require more frequent shiftings than hard-wooded plants, for which an annual renewal is sufficient.—Farm and Fireside.

Garden and Field Crops

CALIFORNIA SEED RAISING CENTER.

In 1793 Cooper, Taber & Co., of London, England, the greatest seed growers and merchants of the time, offered to the public seven varieties of Sweet Pea seed. Today the same firm offers, from a complete list, at least 700 varieties and the majority of them are raised in California.

"Truly, the world is turning 'round."

S. B. Dicks, fellow of the Royal Horticultural Society of England and member of the firm of Cooper, Taber & Co., said as much in a recent interview with a Los Angeles (Cal.) newspaper representative. Mr. Dicks is making his annual tour of the United States in the interest of his firm. Incidentally, a member of the firm has visited the United States for the past 82 years, without exception. Nowadays, the tour is not complete without a visit to California.

"The time was," Mr. Dicks said to the reporter, "when England sent seed to California. Now California is sending seed to Europe and that is why I say the world is turning 'round. At one time California was sending its money to England for the seeds that were necessary in its development. Now we are sending our money here for seeds that we distribute to the world.

"There are three special kinds of seeds in which the trade of Europe has been transferred to California, and to Los Angeles, I may say. First, there is the lowly onion. The onion is grown to greater perfection in California than in any other state of the Union or in Europe. At one time we drew upon the East for our supply of onion seed, but now we are coming to California and to Los Angeles. California has given the East a knockout blow, so far as onions go.

"Second, there is the seed of the lettuce. Lettuce is grown by the hundred thousand pounds in this state, I find. The seed is of particular value because of the state of perfection which it reaches. This climate allows it to grow to greater maturity and, consequently, it is more hardy, and even after two or three years is as good for our purpose as it was when first gathered.

"As for sweet peas, this is the market upon which the world draws for its seed. The culture of the sweet pea practically has been driven out of Europe because of disastrous seasons and has settled in California, where hundreds of acres are grown. Again, I say, the climate is responsible. Here the product may be cut, dried and threshed in the open field, while in Europe we are forced to cut, then stack and wait for favorable weather to thresh. All of these conditions have a bearing on the price of the seed. We can buy here and ship to Europe and sell the seed as cheaply there as we formerly did the home-grown variety.

"Germany, for many years, was the principal growing ground in Europe for asters. There, again, climatic conditions militated against the culture of the aster and of recent years it has been practically impossible to get satisfactory seed from Germany. The germinating quality was poor and the seed was deteriorated. Here the aster gets all the sunshine necessary and we find the finest seed now comes from California."

The sweet pea, no doubt, is Mr. Dicks' hobby. He is one of the founders of the National Sweet Pea Society of England, which has done more to foster the culture of the sweet pea than any other horticultural organization. Besides, Mr. Dicks wrote a history of the sweet pea which now is considered an authority.

The house of Cooper, Taber & Co. has been in existence since the time of Queen Elizabeth. The head of the house was at that time a common councilman and Shakespeare was appearing in his Black Friars Theater close to the spot where the London house of the firm now stands.

"I dare say we may have sold Shakespeare himself some seeds, although it is not recorded on our books," Mr. Dicks said this morning. "He probably paid cash, if he bought."—Florists Exchange.

NITRATE OF SODA ON LETTUCE.

A subscriber in Indiana wants to know whether or not it will pay to use nitrate of soda on lettuce. He desires to apply it with spray pump just before watering with hose. He also wants to know how much to use per 1000 square feet of bench space and where it can be purchased.

Nitrate of soda is not generally used with lettuce in the greenhouse. Manure is used so freely that the soil is usually full of available plant food. There are cases no doubt when nitrate of soda would increase the crop to such an extent that it would be a profitable investment. The best way to determine whether or not your soil needs the addition of nitrogen in the form of nitrate of soda would be to use some of it on a part of the area and leave the rest without the addition of nitrogen in this form. The quantity applied per 1000 square feet might be varied. Twenty pounds per 1000 square feet would be a heavy application, while ten pounds would be comparatively light.

I can see no reason why the nitrate of soda should be applied in the form of a spray. Nitrogen in this form is readily available and if it is worked into the soil just before setting the plants it will dissolve and be ready for the plants as soon as they are ready for it. Nearly all dealers in commercial fertilizers will order nitrate of soda if they do not have it on hand, but they sometimes have to be urged to do so as they prefer to sell mixed goods as a rule. It often comes quite lumpy and should be mashed or ground up before applying to soil.—Market Growers Journal.

All spices should be plainly labeled. Not having cans already marked, use laps of envelopes. Write or print on them what you want. Use on either cans or bottles. The envelopes need not be wasted, as they may be used for holding recipes or clippings.

Carneaux Pigeons—Guaranteed thoroughbred; original stock purchased from Plymouth Rock Squab Co., Boston. Four weeks squabs, weight twelve to twenty ounces. Breed ten times a year. Guaranteed mated and working when sold. Write for particulars. W. C. Barrett, Carneaux Squab Co., San Pedro, Cal.

FARM LANDS FOR SALE.

For Sale—By owner, good farm land, $50 per acre, in Merced County, 9 miles from Merced and ½ mile from station on S. P. and 4 miles from La Grande on Santa Fe. This land is a rich, sediment soil, situated in the Artesian Belt and an abundance of water is thus assured. Is level and all under cultivation. No alkali, and is suitable for figs, corn, alfalfa, beans, and all farm crops. Will subdivide in lots from 40 to 1000 acres. This land is very cheap at the price. In fact, it is only one-half the price of other land in same locality. For further particulars call or address Paxton, 612 Lankershim Bldg., Los Angeles.

For Sale—A 20-acre farm for $20 cash and $20 a month; possession now; $90 to $125 per acre; your crops pay for the land. Rich, level land for alfalfa, oranges, almonds, grapes, cows, chickens; abundance of ditch water, for irrigation, for $1 an acre a year. Where else can you get this? In Oakdale Colony, near good town and railroad station, climate delightful. T. Wiesendanger, 207 S. Broadway, Los Angeles, Cal.

For Sale—Mountain home near Riverside. 160 acres hill land with concrete buildings in excellent repair, and 140 stands of bees in fine condition. Good spring close to house. Ideal location for healthseeker or chicken raiser. H. E. Wilder, R. F. D. 1, Riverside, Cal.

For Sale—815 acres in San Luis Obispo County. A typical dairy ranch. Plenty of wood, water, irrigable land, buildings, fenced and cross fenced. Orchards, vineyards, oranges, lemons and walnuts do exceedingly well here. Forty acres of land suitable for these. Price $21 per acre. For further particulars apply to Mrs. F. A. Clink, Pozo, Cal.

For Sale—The Fresno Meadows Colony is now opened for settlement in lots of 40 acres or more with water at $50 per acre. This is an opening price and is made to induce settlement. Arrangements can be made so that the first payment will carry the deal indefinitely. Call or write at once. Green & Webb, Gen. Sales Agents, 406 Laughlin Bldg., Los Angeles. Phone A8284.

San Joaquin Valley alfalfa land for sale with railroads, schools, electric power and cheap water at hand. 40-acre tracts and up at reasonable prices. Also several large stock and alfalfa ranches with artesian water. C. H. Biggin, Pixley, Tulare Co., Cal.

For Sale—11.85 acres full bearing peach orchard near Ontario, being lot 4, block L, of Blackburn's Addition to Ontario. Price $2200.00; $1300.00 cash, balance in one, two and three years. Address, O. Sassaman, Perris, Cal.

Irrigated Land—The famous Gridley Colonies. Improved lands, best homeseekers' proposition in California. Write for particulars. Gridley Land Co., Gridley, Cal.

Cuba—Most productive soil. Delightful and healthful climate. Ample rainfall. Cheapest transportation facilities to the world's greatest markets. Particulars free. Sanderson, 13 Palace Building, Minneapolis.

For Sale—Near Lancaster, Cal., bargains in improved and unimproved land. Also relinquishments for sale or trade. Some homestead land. A. S. Burnham, Box 451, Lancaster, Cal.

Information where there is good state land in California now. Where? How to obtain. Send dime. Total cost $2.00 an acre. Joseph Clark, 830 M St., Sacramento, Cal.

Apple Orchards—Large and small, in the only apple producing section in California. The greatest section west of Missouri River. Write for booklet. Geo. W. Sill & Co., Watsonville, Cal.

SUCCESSFUL INCUBATION
Typhoid, Malaria, Diphtheria and other dreaded diseases are largely caused by drinking impure water. Our "Seneca" filter will positively remove all germs and other impurities from water, leaving it "Clear as Crystal" and absolutely pure. The "Seneca" filter is on sale at hardware stores generally. If your dealer does not carry it, we will supply you direct. Everyone should have a copy of our Free Booklet, which tells about the diseases caused by drinking impure water and how the "Seneca" **siphon & pressure** filters remove all impurities. **The Seneca Filter Co.**, Dept. D, Kans. City, Mo.

PURE DRINKING WATER
This book written by Mr. P. Cook of the Mammoth Hatchery has eagerly been looked for. It is the authority on all questions connected with the hatching of chicks. There are no theories, but reliable information. Shows how to test carbonic acid gas, moisture, etc. Explains the cause of chicks dying in shell and how it may be prevented with certainty. This book will enable anyone to make his incubator hatch as fine and large chicks and as many as the mother hen. Price $1.00 postpaid. The WEIMAR PRESS, 3015 S. Main St., Los Angeles, Cal.

MAMMOTH HATCHERY
75,000 eggs in incubation. We sell the finest, strongest baby chicks in the world. All from pure bred stock. Prices 10 to 15 cts. We are the largest dealers in fine laying hens. We ship everywhere. Send for our new catalog. Free. Largest stock of second-hand incubators. P. Cook, 3017 S. Main St., Los Angeles, Cal.

General Household Notes

INTRODUCING MYSELF.

I'm not the fellow you read about,
But only the man you know,
The chap you meet on the busy street
Where the hurrying thousands go;
I cannot class with the "starving poor,'
Nor yet with the "men of means";
I'm just the sort that you are yourself—
The salaried "in-betweens."

I've never handled a spade or pick,
I'm hardly a "son of toil,"
I cannot plow, for I don't know how
To "wrest my bread from the soil";
I'm only an ordinary dub,
With commonplace things to do,
And so, O commonplace friends of mine,
I'm singing my songs to You.

If you've never made your summer suit
Suffice for the winter's chill,
If you've never gone with a soiled shirt on
To save on the laundry bill,
If you've never eaten a buffet lunch
To save a nickel or two,
If you've never worried about the rent—
These ballads are not for you.

But you who worry and puzzle out
Each item of daily life,
Who work and fret in the fear of debt,
Along with your faithful wife—
Maybe you'll find in these songs of mine
A strain that you know is true,
And though I'm hardly the soul of song,
I'm singing them all to You.
—Berton Braley, in December Pacific Monthly.

* * *

The farmer often has his blues and bad "streaks," but "the salaried in-between" isn't always in the enviable position which he has in some farmers' imagination.

THE PASSING OF "FAITHFUL SCOTCH."

The above is the heading of an editorial which appeared in the Chicago Inter Ocean in June, 1910. It is another tribute to one of those loyal friends of man whose affection, devotion and intelligence make it difficult for many of us to believe that death blots out of existence the life of which they are the manifestation. The substance of this editorial we are glad to give here:

The thousands who will visit Estes Park in the Colorado Rockies this summer will not see "Faithful Scotch." For this famous collie of a famous master has gone where the good dogs go.

Scotch's master — or rather the friend and companion whom he worshiped—is Enos A. Mills, known in this country and abroad as the guide to Long's Peak, nature student and enthusiast, government lecturer on forest preservation and author of "Wild Life of the Rockies"—of which one of the chapters not least interesting is devoted to the doings of "Faithful Scotch."

Mountain climbers come from all over the world to ascend Long's Peak, a picturesque mountain of over 14,000 feet, just this side of the Continental Divide. Mr. Mills has been the guide of this mountain for more than twenty years and out of the situation have grown the little rustic hotel and log cabins of Long's Peak Inn (where go the climbers to begin the ascent.

Of this little rustic inn Scotch was no less the host than his master. He welcomed the coming and sped the parting guest. He escorted the climbers to the trail up the Peak. He received the returning fishermen. He kept the burros on the other side of the brook. He stood between the coyotes and the inhabitants of the chicken yard. He played football with the guests after dinner.

No matter how dogmatically the "instinct" school of scientists may assert that animals do not reason, Scotch had a mind of his own and used it—as any one could see who had eyes. A catalogue of his exploits would fill a book.

For example, when Scotch was but two years old a pack of coyotes made his life miserable. He went fifteen miles and brought back another collie. That afternoon the two dogs played as neat a game on the coyotes as ever was seen, and taught them their lesson for all time. That night the visiting collie returned home.

Again, a strapping young woman, accustomed to mountain climbing, insisted upon ascending Long's Peak alone. Guide Mills assented, but sent Scotch with her. The young woman got to the summit safely, lingered too long and got caught in the darkness and a storm.

When she went wrong on the downward trail Scotch, who knew every inch of the Peak, did his best to get her back. But the woman was obstinate. Scotch stayed with her on the mountain, kept her warm and saved her life. She was rescued at daylight slightly frostbitten, but otherwise all right. When the rescuers arrived Scotch gave a yawp of disgust and dashed off home for some breakfast.

Once Scotch misunderstood his orders and unflinchingly faced death in carrying them out—as he understood them. His master sent him back on a wilderness trail in winter to find a lost mitten. Twenty-four hours later in the bitter cold, his anxious master, after twelve hours of desperate climbing, found Scotch lying on the mitten. He thought he had been told to guard the mitten, not to bring it back!

The manner of the passing of Scotch is at once a pang and a consolation. Death by accident is always cruel because seemingly needless. But he died in doing what he thought was his duty.

The sin of sins in a forest country is to leave fire, and the first duty of the man who finds fire in the forest is to put it out. Scotch knew this as well as any one—many an incipient fire he had put out with his feet and many an alarm had he given.

This spring Scotch paid a visit to the roadmenders, and, as fate would have it, he arrived just at the moment when the men had taken shelter from a dynamite blast. His vigilant eye detected the smoke of the burning fuse. He barked the alarm and dashed to the spot. He arrived just as the blast exploded. He was struck in the head and chest. Death was instantaneous.

HOMELY HINTS.

When making cooked starch put in a bit of lard, and note results.

Wet a cloth in coal-oil and use to clean the sink; dampen another with the oil and rub your nickel-plated teakettle while hot. It will shine like silver.

An excellent and simple method of making a lamp throw out a clear light is to place a small piece of gum camphor in the receptacle with the oil.

To mend a crack in a stove, mix three teaspoonfuls of salt and one

---When in Need of Furniture, Rugs, Carpets, Draperies, or other Household Goods, Buy of Barker Bros.,

The Leading Furniture House of Western America.

Our immense store, with 150,000 square feet of floor space, contains the largest stock of household and office furnishings shown in any establishment west of the Mississippi River. Largest assortment in all lines; lowest prices on all grades of goods; best terms for all classes of buyers.

Buy Your Furniture by Mail

If you cannot visit our store in person, we will furnish prices, together with pictures of any articles of furniture upon our floors. We pack goods carefully, and ship promptly to any point. It will pay to buy of us, even though you live a considerable distance from Los Angeles.

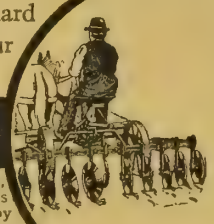
Increase your orchard yield

Bigger better fruit and more of it will be the result if you use the Planet Jr No 41 Orchard and Universal Cultivator to give your orchard thorough cultivation.

Planet Jr.



No. 41 is the greatest help you can have in orchard, vineyard, and hopyard. Saves time and labor besides doing better work. It is built especially for your work by a practical farmer and manufacturer, with over 35 years' experience. Unusually strong construction, yet easily handled. Equipped with attachments which cultivate, hoe, and furrow to any desired depth; also has side-hitch and fruit and tree shield. Can be made into disc-cultivator. Every implement fully guaranteed.

We carry stock in San Francisco. Agencies in all principal Pacific Coast cities. Write for name of nearest agent. Send for our new illustrated catalogue of 1911 Planet Jr implements, describing tools for every farm and garden use. Free.

S L Allen & Co Box 1106P Philadelphia Pa

pint of wood ashes with sufficient water to form a stiff paste. Fill the crack with this mixture while the stove is hot. When dry it will be as hard as cement.

If a beaten egg and a slice or two of light bread, soaked, are added to Hamburg steak, the latter will not become so dry and tasteless when fried.

To clean and brighten a galvanized iron pail or washtub use chloride of lime dissolved in soft water, and kerosene; rub, then polish with a soft cloth.

When washing cream-colored curtains add yellow ochre to the starch until the tint is as deep as you wish it to be. Test it with a bit of lace before dipping your curtains. Five cents' worth of the ochre will be sufficient for six pairs. Other laces may be tinted in like manner.

If, when you are cooking meat, fruit or vegetables, they should burn, remove the kettle from the fire and set immediately into a pan of cold water to remain until cool; then take from the kettle and put over the fire to cook again, being careful not to put in any burned pieces. You will not know by the taste that the food was scorched.

Soap-bark is one of the best things I know of to cleanse woolen fabrics. Procure a package at your druggist's, steep a pinch in water, and strain, and use the tea to sponge the article thoroughly. Coat-collars, so hard to make presentable, are readily cleaned with soap-bark, prepared as directed. It is better and safer than gasoline.

If you wish to darn a tablecloth, stretch the worn place or rent in your embroidery-hoop and see how much neater your work will look; it is more quickly and easily done, too. Also in darning the legs of children's stockings, try the plan of first buttonholing the hole, then darning from the buttonholed edge. The finished work is neater and more durable.

Take a tin lard pail, one that holds about five pounds, and punch the bottom full of holes, which you can easily do by placing it on a hard-wood block and using a large, long wire nail or punch to strike from the inside. Wash knives, forks and spoons, put them in this pail, pour scalding water over them and in a short time they will be dry, needing only a little wiping. Do the same with plates and most other dishes.

How many of the women folks use kerosene for taking paint out of garments, and for removing spots from boys' clothing? Just saturate with kerosene, rub well with a dark cloth, then hang in the air. I have taken enamel out of flannel, after it was pressed in, by this simple method. the oil soon evaporates, and will not harm any fabric.

A girl's education is not complete unless she has learned: To sew, to cook, to mend, to be gentle, to value time, to dress neatly, to keep a secret, to avoid idleness, to be self-reliant, to darn stockings, to respect old age, to make good bread, to keep a house tidy, to be above gossiping, to make home happy, to control her temper, to take care of the sick, to take care of the baby, to sweep down cobwebs, to marry a man for his worth instead of wealth, to read the very best of books, to take plenty of active exercise, to be a helpmate to her husband, to keep clear of trashy literature, to be light-hearted and fleet-footed, to be a woman under all circumstances.—Coleman's Rural.

LLOYD R. TAYLOR, Modesto, Cal.

Continued from Page 108.

ordinary precautions are observed; colds and the dreaded disease, roup, seldom if ever affect fowls kept in houses of this kind.

The following size will house a dozen or more fowls:

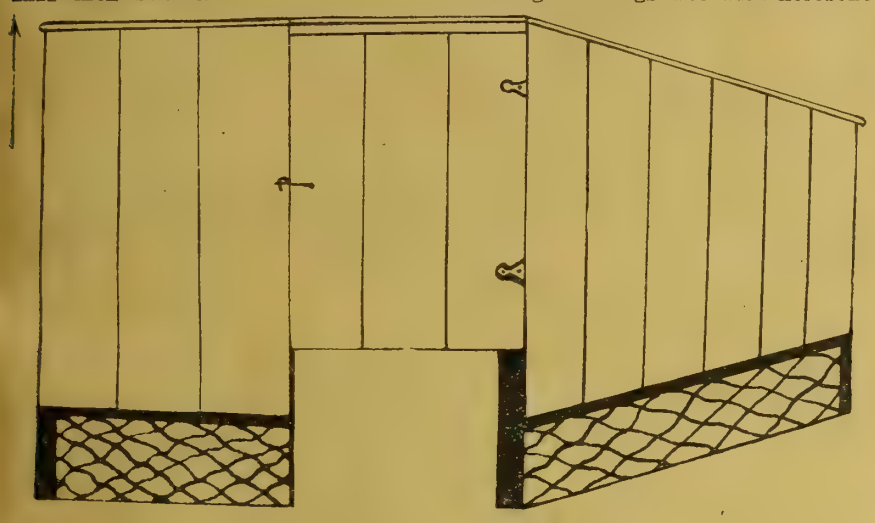
Dimensions of Poultry House.

Front—6 ft. high.
Back—5 ft. high.
Length of Front—6 ft.
Length of Sides—5 ft.
Door—2½x4 ft.

One foot of wire netting around entire bottom except at door.

Cost to build, complete—$6.00.

For material use four uprights, 2x3 or 2x4 in front, back and sides use 1x12 inch boards.



A LOW COST CALIFORNIA POULTRY HOUSE

Roof can be covered with any kind of roofing material, but for a permanent roof, shingles are best. One bunch or seventy-five cents worth is sufficient. 22 feet of 2-inch mesh wire for the lower part of the house will cost about fifteen cents. It will require 150 to 200 feet of lumber to build the house, which at $30.00 per thousand would make cost of house $6.00 when complete if all new material is used. If, however, old material on hand is used, the cost would simply be the labor.

Wire netting should extend around the entire bottom, except under the door, which can be left open for entrance or it is not necessary to have wire at the bottom. It is used or not according to one's needs.

If exhibition stock is kept in these coops the entrances should be two feet high to keep tail feathers from being injured. One foot entrance is high enough for common fowls.

The owner can use his own judgment as to having an opening for entrance or a door or a slide.

The inside of the house above the wire should be wind and waterproof, all ventilation needed is at the bottom. The air passing under the fowls and through the wire from all sides insures perfect ventilation and pure air regardless of the number of fowls housed.

The roosts should be one and one-half to two feet above the ground, but in case of heavy breeds that cannot fly high, the roosts could be lowered and the opening at the bottom made less than one foot, but in any case have the fowls roost above any possible drafts. Have simple roosts. A 1x3-inch strip makes a good roost for 5 or 6 feet. Nothing but roosts should be kept in the house unless it is convenient to have nests there. The nests should be set on the floor and not made fast to any part of the house. They can thus be easily removed and cleaned with fresh straw, grass or whatever nest material is used.

Paint the outside of nests, and the ends, sides and bottom of roosts with any good liquid lice killer. This treatment will keep out vermin.

Fix the roosts so they can be easily taken out and returned to their place.

SCALY LEG.

Scaly leg is contagious and is caused by a parasite mite, commonly called a scab mite. Dissolve in kerosene all it will take up of crude naphthalene flakes. Dip the scaly legs in this solution, taking care not to get the soft parts above the hocks wet with it. If soft feathered parts get wet with kerosene it will raise a bad blister. For same reason apply remedy in day time and not at night, as roosting with legs wet with kerosene may result in blisters on breast. Let fowl run after treating. Repeat the treatment every second day for three or four applications, then wash the legs well with good yellow soap and warm water. If necessary treatment may be repeated in a few days.—American Poultry Journal.

The laying of unusually large eggs is an indication that the hens are too fat.

ARNOTT DOUBLE DISC HARROW

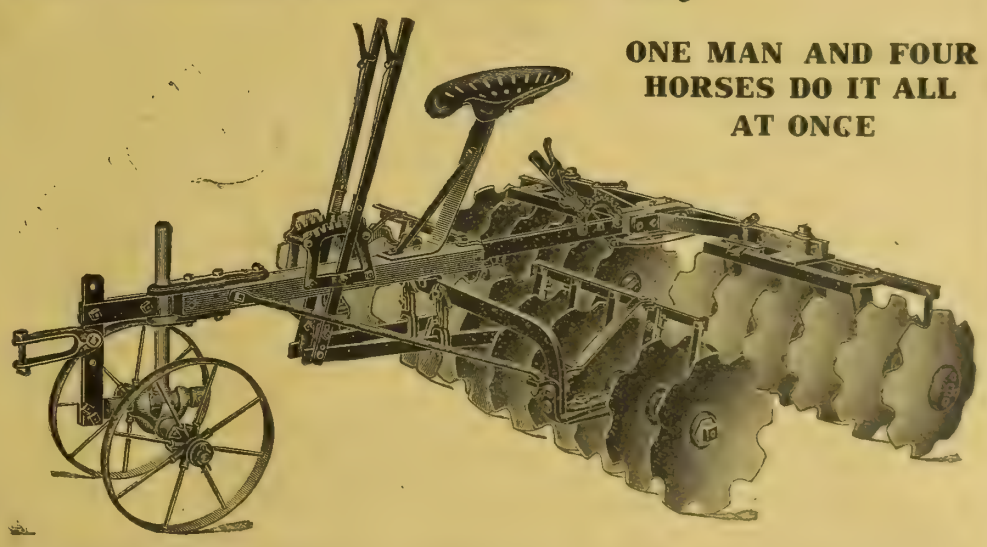
A Plow—A Disc—A Pulverizer—A Smoothing Harrow all in one

The SENSATION of the Day

Compare it Point for Point With Any Disc Harrow Made

Double Gangs
Double Cut
Double Throw
Double Levers

ONE MAN AND FOUR HORSES DO IT ALL AT ONCE



The flexibility of the **Arnott "Double-Cut"** in contrast with the stiff action of other two-way harrows is what is making it so popular. This flexibility is possible because of our Universal Joint connecting the front and rear gangs. For lack of this feature other double harrows have a good deal of side draft and will not make a square turn without digging a great hole. This can't happen on the **Arnott.** Independent front and rear levers within easy reach of rider.

Complete description mailed upon application. Write for prices

ARNOTT & COMPANY, Inc., Southwestern Gen. Agts.

Beeswax, lb	24@30

Scott, Magner & Miller say:

During the week ending today the San Francisco market has received 2,250 tons of hay. This amount is considerably less than we received during last week, and the cause of the lighter arrivals this week can be found in the fact that it has been difficult, and in some places impossible, to load this week on account of weather conditions.

Considerable hay has been ordered into market, and as soon as weather conditions are satisfactory for loading, arrivals can be expected to be sufficiently active to supply all branches of the trade.

There has been some little movement of alfalfa hay recently, and a better demand has been in evidence. Prices have remained steady and unchanged on this article.

We quote the wholesale prices in round lots on today's market as follows, viz.:

Fancy wheat	13.50@14.00
No. 1 wheat or wh and oat	11.50@13.50
No. 2 wheat or wh and oat	10.00@11.00
Choice tame oat	12.00@12.50
Other tame oat	9.00@11.00
Wild oat	8.00@10.50
Stock hay	6.00@7.00
Alfalfa, ton	9.00@12.00
Straw	40@50

Grain.

Wheat, No. 1	1.42½@1.52½
Barley, fancy	1.16¼@1.17½
Barley, good to choice	1.12½@1.15
Barley, poor to fair	1.10@1.11¾
Oats, white	1.45@1.60
Rye, new crop	1.50@1.60
Alfalfa seed	18@20
Mustard, brown	4½
Millet	2¾
Flaxseed	5@5½
Broom corn seed, ton	23.50

Feed Stuff.

Almonds

The exchange almond stock is now reduced to 20 cars and the inquiry still continues good; in fact, we advanced the price ⅛c on one variety last week and the offer was promptly accepted.

Ne Plus are nearly cleaned up, as are also Languedocs and Hardshells; Drakes are moving rapidly and IXL's are moving very satisfactorily.

We have also arranged for all the balance of our shelled stuff and have inquiries for still more, which we will take care of before long.—California Almond Growers Exchange, J. P. Dargitz, Sec'y and Mgr.

Citrus Fruit Market

LOS ANGELES, Jan. 25, 1911.

Spotting of navels still continues to depress the market. Some auction sales are made at ruinously low prices, but, the country over, the sales are not so discouraging. The lessening of shipments which present weather will force will probably succeed in strengthening the market.

Lemons are very firm and commanding fair prices.

Shipments.

Shipments of oranges to date since Nov. 1, 1910: 6,090 cars, lemons 932 cars, total of citrus fruits 7,022 cars. To same date last season: Oranges 3,303, lemons 905, total 4,208.

NEW YORK, Monday, Jan. '23.—Twenty-nine cars navels, one car lemons sold. Market higher on medium and small sizes. Lemons higher. Fair and seasonable.

LEMONS—Homer, Q C, Corona, $3.55.

CHICAGO, Monday, Jan. 23.—LEMONS—Under a moderate supply the market is firm. A fairly active trade continues. Boxes, California fancy, 300s, $3.50 asked; 360s, $3.25 asked; off sizes, $3.00 asked; extra fancy, $3.75; extra choice and choice, 25c per box discount.

ORANGES—For navels there is a steady market. Demand is fairly active, and they are in good supply. Boxes, navels, California fancy, 96s, $2.25@2.50; 126s, $2.50 asked; smaller sizes outside in rather a small way,

LACK OF RAIN DOESN'T WORRY THESE FARMERS

Last year several hundred farmers decided that they had worried just about long enough over lack of water. So they bought I H C Gasoline Engines and installed irrigation systems of their own.

Now they have the most practical kind of crop insurance and they are independent of the irrigating companies.

Nearly every farm has a creek, slough, pond, or some other source of water supply that can be turned into a valuable asset by the installation of an

I H C Gasoline Engine

Why not put yourself in a position to have water where and when you want it—irrigate your entire farm if need be?

I H C Engines are admittedly the best power for this purpose. They require but little attention and their superior efficiency and economy have been proven by years of service. In addition to running your irrigating system they will do a host of other things such as running a cider press, alfalfa cutter, feed grinder, saw, washing machine, cream separator, etc., better and cheaper than any other power. There are all styles and sizes to choose from, 1 to 45-H. P., horizontal or vertical—stationary, portable, or traction.

Call on the I H C local dealer and let him show you the one best adapted to your needs; if you prefer, write direct for the I H C Engine catalogue.

I H C Service Bureau

What is it? A clearing house of agricultural data.
What does it do? Helps farmers to help themselves.
How can it be used? By sending your farm problems and puzzling questions to the Bureau.
We are co-operating with the highest agricultural authorities and every source of information will be made available to help solve your difficulties. We shall be pleased to have an opportunity to assist you. Write the I H C Service Bureau

One Animal and Three Hogs to an Acre

THIS is a fair estimate of the average feeding ability of the soil. On a farm of 80 acres the highest limit of efficiency is 20-acre fields. Large fields diminish the earning power because two small fields alternated will furnish much more support for stock than the same average in one big field. The fence is the important factor; and with the liberal use of gates, unlimited extension and alternation is simple.

The steel in Ellwood fence is specially made from carefully selected stock. It is hard, elastic, tough and springy. The line wires, composed of two or more wires twisted into cables, give each individual wire the shape of an elongated, coiled spring. The fence is therefore sufficiently elastic to take care of expansion and contraction, and yet so rigid when properly stretched as to prevent sagging. The small and permanent mesh is made by weaving one continuous wire throughout the fabric. The mesh or stay wires are so interwoven that slipping is impossible. The triangular truss is the strongest form of construction known. For this reason, Ellwood fence will stand the hardest usage and still retain its shape.

Ellwood Fence is sold in your town. Look for the Ellwood dealer and let him show you his different styles of fence and quote you his low prices. Get his expert advice on your special needs. He is on the spot, buys in large quantities, gets the lowest carload freight rates, demonstrates quality before your eyes and is the man from whom you will get the most for your money.

The Big Weekly { Fifty-two issues, each containing from 24 to 32 pages of practical information, } For $1 the Year

California Cultivator

An Illustrated Weekly devoted to Horticulture and Agriculture

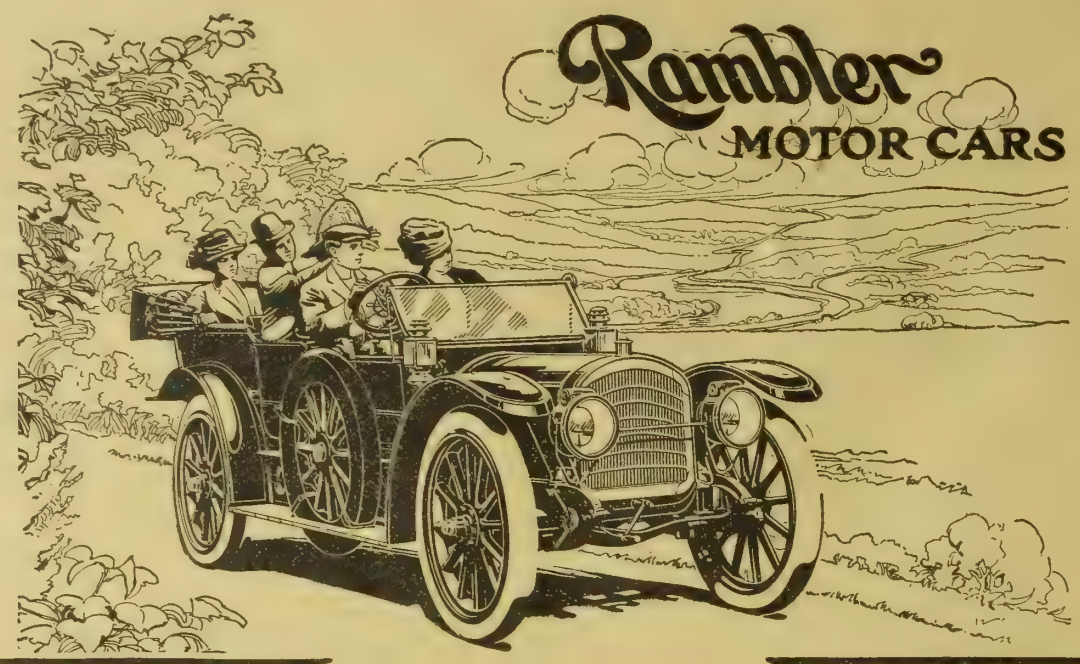
LOS ANGELES FEBRUARY 2, 1911 SAN FRANCISCO

STANDARD BRED S. C. BROWN LEGHORN COCK.

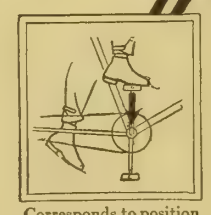
It was the intention to publish this "counterfeit presentment" of a pure-blooded Brown Leghorn cock in the Cultivator for last week, but our friends being unusually generous in their contributions to the annual poultry number, it was unavoidably crowded out. No breed of poultry has a stronger following in this state than the Leghorns, the white variety of which predominates almost to the exclusion of the Browns, Buffs, Silver Duckwings, Piles, Cuckoo, Mottled and the Blacks. Barring the last five which are bred but sparingly (and that chiefly by fanciers), the Browns and Buffs possess economic values quite as pronounced as the White. In type, head and leg points, habits and temperament, there is no great difference, the line of cleavage being almost wholly in the color scheme in plumage. Bred to feather, both varieties are indeed handsome birds, appealing strongly to the fancy. They "come" true to type, but in feathers there is still a tendency to mealiness in under color, with here and there an "off" feather in the surface. When, however, up to Standard, the bird is an object of beauty and admiration.

The Leghorns are proverbially rapid growers, good foragers, light eaters, and, what is of more consequence, prolific layers of white-shelled eggs. It has been said that, bird for bird, they require less attention from the caretaker than many of the heavier breeds. They like freedom, hence, when kept in close quarters, care must be exercised in keeping them active—in other words, at work. In Petaluma, where the Whites are kept in large numbers, the colony plan is quite generally practiced, which affords range and activity. In the early days Brown Leghorns were not uncommon in California, but of late years other breeds have outnumbered them in popularity, which is nothing against the breed. There are fashions in hens, as well as in ladies' hats.

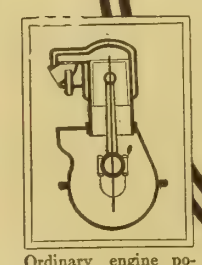
Rambler MOTOR CARS



Rambler Sixty-five Forty-inch Wheels



Corresponds to position of crank shaft in ordinary engine at explosion center.



Ordinary engine position of crank shaft at explosion center.

THE Rambler Offset Crank Shaft is a necessary advantage in a car to be used on country roads or in crowded city traffic. It enables you to throttle down on high gear no faster than a man usually walks, or glide along slowly on high gear behind a heavily loaded wagon. You take the hills easily, as there is no need to rush the hard pulls, and much gear shifting is avoided. Notice a man about to mount a bicycle. He always adjusts the pedal in that position where it will receive to best advantage his full weight on the first downward stroke. This position for the pedal is slightly forward of the center of the crank shaft of the bicycle. If he mounted when the pedal was directly over the center of the crank shaft, his weight would fall directly on the bearing and the first downward stroke would be retarded and, therefore, weak. In the Rambler motor, at the time of greatest pressure the connecting rod is perpendicular, and the crank shaft in a position to receive the greatest power from the explosion. This feature, with the Straight Line Drive, big wheels and tires, Spare Wheel and accessible Engine, is most appreciated by the experienced owner.

The new catalogue is ready. Send for it. Tell us the kind of car you like and we will mail you the Rambler Magazine.

The Thomas B. Jeffery Company

Vol. XXXVI. No. 5. LOS ANGELES: THURSDAY, FEBRUARY 2, 1911 One Dollar the Year

The Horticultural Value of a Great Institution

An Organization formed Five Years ago which has had Wide Influence for the Good of the Citrus Industry of California.—A statement from G. Harold Powell, secretary and manager of the League.

The Citrus Protective League of California is a voluntary organization, formed in March, 1906, by representatives of growers, shippers and shipping organizations in nearly all of the citrus growing localities in the State to handle the public policy questions that affect the industry as a whole. Its purpose is to represent the grower and shipper in handling such questions as, railroad rates and transportation problems; customs tariffs and other governmental relations; State and Federal legislation that applies directly to the business, and all other questions of a general nature that affect the upbuilding of the industry, except the marketing of the fruit.

The League is directed by an executive committee of nine and by a secretary and manager, the executive committee having been appointed by an administrative committee of thirty of the principal growers and shippers who act as a governing committee.

The citrus industry represents from $150,000,000 to $200,000,000 capital invested, 10,000 growers are interested in the cultivation of the fruit, 100,000 people depend on it for a livelihood, and nearly 50,000 carloads are expected to be shipped from the State during the present season. No other agricultural industry in America is so highly specialized. None is more closely tied together by common interests. None is brought more closely in contact with organized business interests from the grower to the consumer, and as a result has larger and more far-reaching general questions confronting it.

The League is supported by funds raised by general assessment based on the number of cars of fruit shipped by each member during the preceding year. Fourteen assessments were levied to December 31st, 1910, and $68,654.88 have been paid in by the members in the five years since the League was organized, of which approximately $65,000 was expended in the management of its business to December 31, 1910.

The League has played an important part in the progress of the citrus industry in the past five years. In 1907 it induced the railroads to reduce the freight rate on oranges 10c per hundred pounds, from $1.25 to $1.15. This rate became effective February 26th, 1907, since when it has saved the shipper from $28 to $30 per car. The gain to the industry from February 26th, 1907, to December 31st, 1910, from this reduction has been about $3,175,000, or about 45 times the entire cost of the League, from the date of organization to the present time.

Following the reduction in the freight rate and as a result of the succeeding agitation accompanying the refrigeration rate question, the railroads changed the refrigeration tariffs allowing 32,000 pounds of fruit to be shipped in a 40-foot car at the same rate per car for refrigeration as applied before on 27,650 pounds. This change became effective July 5, 1909. It is estimated that the value of this change to the shipper is approximately $35,000 to date, or more than half of the entire cost of the League since its organization.

In 1908 the League began a movement to prevent the duty of one cent per pound on oranges from being reduced by Congress and to secure an increase of one-half cent per pound on lemons for the purpose of covering the extra cost in labor expended on the lemon above the labor cost expended on the orange. Through the aid of the Senators and Representatives from California the League was successful in both of these efforts, the duty in the Payne-Aldrich bill standing at one cent per pound on the orange and one and one-half cents per pound on the lemon. The new tariff law became effective August 5, 1909.

"The citrus people of California are making history. You who are in close touch with this great industry, have no conception of the influence this organization and its methods has upon the people of the East and of Europe, who are watching it. My connection with the Department puts me in position to know the great number of inquiries made as to methods and successes in handling the citrus business, and which have to do with the entire industry."

The above words were spoken by G. Harold Powell, the new head of the Citrus Protective League. Mr. Powell has been drawn to this work from his important position as acting head of the Bureau of Plant Industry by a desire to be a factor in the history making which the citrus industry is engaged in. It is true that all believe Mr. Powell will be a great factor in his new field. It is not, however, entirely new, for all know of his great work under the Department in the successful campaign made to prevent decay of citrus fruits while in transit. That campaign saved millions to the citrus industry. Mr. Powell is taking hold of his new work with characteristic vigor. Facts are being gathered, while data already in the office is being systematically classified ready for use at a moment's notice. This page gives a statement by Mr. Powell as to the past work of the League, as well as its future problems.

The League made an investigation of the methods used by the Government in determining the amount of decay in imports of lemons and in refunding the duty to the importer on the same. The League determined that the Federal system gave an advantage to the importer that was detrimental to the California citrus interests. It presented the matter to the Honorable Secretary of the Treasury before whom it laid the data accumulated. A great deal of consideration has been given the question and it is expected that the Honorable Secretary of the Treasury will promulgate new regulations in the near future which will safeguard the interests of the Government and protect the California industry from further unfair competition.

Two months after Congress advanced the duty on imports of lemons from one cent to one and one-half cents a pound, the railroads, through the Transcontinental Freight Bureau, attempted to absorb part of the duty granted by Congress by advancing the rate fifteen cents per hundred pounds. The League secured a temporary injunction through the Circuit Court of the United States for the Southern District in California restraining the railroads from collecting the proposed increase in rates until a hearing was had before the Interstate Commerce Commission. An action was then brought before the Commission challenging the reasonableness of the increased rate on lemons, and at the same time the reasonableness of the rate of $1.15 per hundred pounds on oranges; the reasonableness of the charges for refrigeration and the lawfulness of the precooling charge of $30 per car were challenged.

The Commission found that the rate of $1.15 per hundred pounds on lemons was unreasonable and that the rate ought not to exceed $1.00 per hundred pounds. The railroads then secured a temporary restraining order in the Circuit Court of the United States with and for the District of Kansas preventing the Interstate Commerce Commission from making its findings effective, and the Circuit Court referred the case to the new Interstate Commerce Court, which is now being organized, for a hearing on the various points involved. In the meantime, the original injunction restraining the railroads from enforcing the $1.15 rate is in effect. Since the granting of the original injunction, the shippers who are parties to the action, have given bond, the 15 cents in dispute have been collected through the League on all shipments and is held by a surety company. The difference between the $1.00 and the $1.15 rate will be returned to the growers and shippers if the finding of the Interstate Commerce Commission is sustained by the higher tribunal. The Commission also failed to find that the present rate on oranges is unreasonable. The Commission has made a special investigation on the refrigeration and precooling charges, the arguments on the cases have been concluded and a decision on these points is expected at any time.

These cases were forced upon the growers by the action of the transportation companies in attempting to absorb a part of the customs duty which Congress plainly intended should benefit the producer. An enormous amount of testimony has been taken by the Interstate Commerce Commission and it now has before it the most comprehensive and accurate data on the problems involved in the production and distribution of the fruit, both from the standpoint of the producers and the railroads, that has ever been brought together. The railroads have been represented by the ablest legal talent in the country and the growers have been forced to protect their own interests at every step in the litigation. The final decision in these cases will have a far reaching influence financially and in other respects on the future of the citrus industry.

The League has had an important part to play in many other questions that vitally affect the citrus industry. It made it possible for the State Commissioner of Horticulture to eradicate the white fly from the State in 1909 by paying the bills as they were incurred, the State Treasury at that time having no funds with which to bear the expense. The Legislature later reimbursed the League for the money so expended.

The problems before the League at the present time are far reaching in scope. The rate cases will require attention until they are finally settled. A determined effort is being made by the importers to have Congress reduce the duties on citrus fruits. A large fund is being raised by the importers, through a tax of 5 cents per box on imported fruit to influence public opinion. The importer is seeking through newspaper and magazine articles, by the employment of special counsel and agents and in other ways common to the use of funds of this character to bring about the desired result. The League is preparing to meet the efforts of the importers. It will endeavor to safeguard the common interests of the orange and the lemon grower by every honorable means whenever the question of citrus duties is raised either by the tariff board or by Congress.

The League will use every effort to bring to the help of the grower special investigators from the State and Federal Governments to study the diseases, the insects, the soil problems, and other cultural, fruit handling and fruit transportation problems that affect the industry. It will maintain an agricultural reference library without expense to the grower and will develop a bureau of information showing the international movement of citrus fruit and other fruits that have a relation to the industry.

The League is the only organization that has been formed by an agricultural industry in America, and probably in the world, to look after the general public policy questions that affect it. It represents 90 per cent of the growers and shippers of the State. The organization is a vital part of the industry, formed to protect and advance its interests. The problems that confront 90 per cent of the industry confront the remaining 10 per cent with equal force, and it is the earnest desire of those who have organized the League, and of its members, that every shipper and grower in the State should stand shoulder to shoulder in meeting and solving their comomn problems.

LARGEST CITRUS NURSERIES IN THE WORLD

Parties contemplating the planting of citrus groves this coming spring will do well to send for our prices soon, as there will evidently be a shortage of strictly first class stock. Write today for particulars, or, better still, pay us a visit so that we may be able to show you just what we have.

Our finely illustrated booklet, "Citrus Fruits," covering the industry from the seed to the market, mailed to any address on receipt of 25c in stamps.

Citrus and Tropical Fruits

CHERIMOYA.

Several fruit growers in California have been successful in raising the custard apple, cherimoya, cherimoyer, or anona cherimolia, Mill. It is considered by many the finest of subtropical fruits and its extended development is expected in sections of California which are comparatively frost free. The fruit sells in the East from $9.00 to $14.00 per dozen, but in California markets usually brings from 30 to 50 cents apiece. One tree which has attracted considerable attention is that on the ranch of the Chas. F. O'Brien Co. at Beverly in the outskirts of Los Angeles. This tree is 15 years old and has large round leaves, six inches in diameter, which makes of it a most striking tree. It has a spread of 20 feet and exceeds 25 feet in height. The fruits on this tree will average 30 ounces in weight, some of them running as high as 37 ounces. It will doubtless be a valuable tree from which to reproduce others of this attractive fruit of the tropics. It is known to grow at an altitude as great as 5000 feet but succeeds best lower than that. The trees are reproduced by grafting two-year old seedlings.

ANONA CHERIMOLIA

HOW FROST IS FORMED.

The atmosphere of the earth always contains more or less moisture in an invisible form. When at a considerable elevation above the earth this moisture, or aqueous vapor, is condensed, clouds are formed; when the process of condensation is more active and the temperature of the air is above freezing, rain falls; and when the temperature of the air is below freezing, snow is produced. When the moisture of the air in immediate contact with the earth is condensed at temperatures above freezing, dew is formed; when at temperatures below freezing, frost is deposited. Frost is, therefore, the moisture of the air condensed at freezing temperatures upon plants and other objects near the surface of the earth.

In the process of frost formation the temperature of the air a few feet above the earth is commonly several degrees above freezing. The surfaces upon which frost is deposited must, however, possess freezing temperatures. The manner in which frost is deposited on plants and other objects is very similar to that in which the air moisture of a room is frozen and deposited upon window glass, the temperature of which has been reduced to freezing by the out-of-doors cold. In the case of the frost on the window glass the process is one that can readily be understood. Some explanation, however, is required of the formation of frost, which requires freezing temperature, when at times a temperature above freezing is registered a few feet above the surfaces upon which frost appears.

There are several processes by which the temperature of plants may be reduced below the temperature of the air which surrounds them. The most important of these processes is radiation, by means of which heat escapes from objects and passes into the surrounding air.

In the frost-forming process heat from the sun which is absorbed by the earth and by plants during the day is lost by radiation at night. During the day the earth both absorbs and reflects the heat received from the rays of the sun, and the lower stratum of air is warmed by this reflected heat. During the night when no direct heat is received from the sun's rays the lower air stratum receives no reflected heat, and, at the same time, heat which has been absorbed by the earth is radiated, or, in other words, it rises through the overlying air, though not necessarily and entirely as sensible heat; that is, heat perceptible to the senses. In the frost-forming process there is another very important factor in the production of cold; that is, the evaporation of moisture from the earth and from plants. The nature and composition of frost require that the air in immediate contact with the surfaces upon which frost forms shall contain moisture. This is moisture that has been stored in the earth in visible form, i. e., in the form of water, and which has escaped from the earth, not as visible moisture, but by the process of evaporation and in the form of aqueous vapor. Some part of the heat stored by the earth during the day is, therefore, lost in evaporating the moisture

contained in plants and in the earth. The heat expended in this process is not sensible, but latent. Heat is rendered latent when it is used to boil away water, and it becomes sensible or liberated heat when the water vapor again condenses into water. It appears, therefore, that the temperature of surfaces upon which frost forms, and of the air in immediate contact with them, is lowered by the evaporation of moisture from the surfaces. The influence of the process does not extend to air a few feet above the ground.

Another method by which plants lose their heat is by convection, by means of which they are chilled by contact with colder air. This process, while important in the presence of freezing air temperatures, can scarcely be considered a factor in the formation of frost proper, which is usually accomplished when temperature observations show the air to be above freezing.

Air arranges itself according to its density or weight. Air in immediate contact with the earth becomes heavier as its temperature is lowered by the radiation of heat and settles in depressions or valleys and over lowlands, causing, at times, frost in lowlying districts, while neighboring higher grounds escape the visitations.

A given quantity of heat absorbed by several substances of different specific heat will produce a different temperature in each; the lower the specific heat of the substance the higher will be its temperature; and besides, different substances have different coefficients of absorption and of reflection. Therefore under the same insolation rocks, clay, vegetation, and other substances come to temperatures that often differ by many degrees.

The air next to earth largely partakes of the temperature of the surface, and in consequence, when the sky is clear, so that incoming and outgoing radiations may progress freely, and the air is but little disturbed by wind, wide variations in the temperature of the thin stratum of lower air may occur over adjacent plots of ground of precisely the same elevation but different covering.—Farmers Bulletin No. 104.

A GAMBLE.

We have interviewed a number of growers lately as to what they were doing for frost protection in their orchards. The majority of them were just taking chances, while a few had a little lightwood scattered through their groves. This is an awful gamble, with the odds against the grower. On one hand he stands to win—what? The saving on the cost of pots that would last for at least five years. These pots cost all the way from $20 to $45 an acre, say the average is $30 and that it would cost $300 to equip a ten-acre grove, and that the cost of oil and tanks would bring it to another $100 or even $200. If the pots last five years and no oil has been used it has cost the grower an average of $100 a year, or $10 an acre and the has been protected all the time and has felt safe. He stands to lose—what? this year's work and a crop that might be worth on the trees $3000. A grower who does not protect his orchard is betting $3000 against $100 that there will be no frost and the chances are against him.—Florida Fruit & Produce News.

Earth worms are beneficial to soil, and their work is more effective in soils filled with humus.

HURST SPRAYERS ON FREE TRIAL

NO-MONEY-IN-ADVANCE
PAY AFTER IT HAS PAID FOR ITSELF

LET US SEND YOU ANY OF THESE SPRAYERS—to try for 10 days, then if you buy, you can pay us cash or we'll wait till you sell your crop, then you can pay us out of the "extra profit." *We pay freight. Wholesale dealers' prices.*

Man-Power Potato and Orchard Sprayer.

Sprays "anything"—potatoes or truck, 4 rows at a time. Also first-class tree sprayer. Vapor spray prevents blight, bugs, scab and rot from cutting your crop in *half*. High pressure from big wheel. Pushes *easy*. Spray arms adjust to any width or height of row. Cheap in price, light, strong and durable. **GUARANTEED FOR FIVE FULL YEARS.** Needn't-send-a-cent to get it "on trial." You can get one **free** if you are **first** in your locality. Write **today.**

Horse-Power Potato and Orchard Sprayer.

For **big** growers. Most **powerful** machine made. 60 to 100 gallon tank for one or two horses. Steel axle. One-piece-heavy-angle-iron frame, cypress wood tank with **adjustable** round iron hoops. Metal wheels. "Adjustable" spray arms and nozzles. **Brass** ball-valves, plunger, strainer, etc. Big pump gives vapor spray. **Warranted for five years.** *Try this machine at our expense with "your money in your pocket."* See **free offer** below. Write **today.**

Fitz-All Barrel Sprayer.

Fits any barrel or tank. Has pressure, [illegible] ball-valves, plunger, strainer, etc. Automatic [illegible] *"Rubber"* about any of our sprayers. Furnished plain, mounted on barrel, or on wheels as shown. *Two years to pay. Not cost a cent* [illegible] *in your orchard. Get one free. See about.* **Write today.**

FREE—**Get a sprayer FREE.**—After you have tried the sprayer and are satisfied that it is just as we recommend it, send us a list of the names of your neighbors and we will write them and quote them price and have them call and see your machine work, and for every Fitz-ALL Sprayer we sell from your list we will credit you with $2.00 or send you check if you have paid cash.

For every Man-Power Potato and Orchard Sprayer we sell we will credit you with $3.50 or send check.

For every Horse-Power Potato and Orchard Sprayer we sell we will credit you $8.50 or send check.

We do all corresponding and selling. All you need do is to show the sprayer. Many have paid for their sprayer in this way. This offer is good for only the **first** order in each locality. Don't delay. **Send the coupon or post card NOW.**

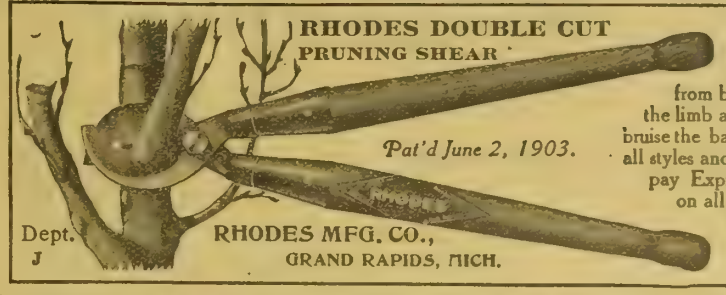
OLD MACHINERY.

Old defective machinery in a packing house is oftimes the cause of more bruising of the fruit than in the prior handling though that often is bad enough. The writer once heard G. Harold Powell of the Bureau of Plant Industry say that he had examined a lot of fruit from the grove of a certain grower as it was delivered to the packing house and found 87 per cent of clipper cuts in the lot, meaning that 87 out of every hundred oranges were punctured.

There was once a certain orange district, with only one packing house, which had a bad reputation for the keeping quality of its fruit. The climate, the soil and various other reasons were blamed. The growers were in despair. They knew they had fine oranges but they would not keep. All kinds of washes were tried without avail. Finally Mr. Powell was called in and upon looking over the plant advised them to put in new machinery. When the old overhead machinery was taken to pieces it was found that bolt and screw heads had been taking their tribute from each orange as it passed through and the reason of the decay was shown at once. Since the installation of the new machinery the fruit from this house is one of the leaders in the markets of the country.—Fruit and Produce News.

Three and one-half tons of manure adds one ton of organic matter to the soil.



RHODES DOUBLE CUT PRUNING SHEAR

Pat'd June 2, 1903.

THE only pruner made that cuts from both sides of the limb and does not bruise the bark. Made in all styles and sizes. We pay Express charges on all orders. Write for circular and prices.

Deciduous Bush-Tree Fruits

PREVENTING INJURY TO YOUNG TREES BY RABBITS.

Considerable loss may occur by rabbits girdling trees. Painting the trunk of trees with either of the washes mentioned in the following formulas will prevent the injury if properly done and in time.

Formula No. 1. Slake in water over night the quantity of unslaked lime needed for the work. In the morning add enough water to make a good thick wash. Stir the mixture well, and to each 2½ gallons of the wash add two tablespoonfuls of Paris green. Take care to mix well in the wash. Apply to the trunk of the tree with an ordinary paint brush; keep the wash stirred up so the ingredients will not settle to the bottom of the pail.

Formula No. 2. Slake the lime as above and stir in just before using in place of the Paris green from one-half pound to one pound of arsenate of lead to each pailful of the wash. A handful of salt added to the wash will make it stick better to the trunk of the tree. Apply this wash in the same manner as in No. 1.

Formula No. 3. Take equal parts of unslaked lime and cow manure and add enough water to make a thick wash, and apply with a brush. This makes a cheap and effective remedy to keep rabbits from gnawing young trees.

Formula No. 4. Make a wash of equal proportions of sulphur, stove soot, and unslaked lime. Put in enough water with these ingredients to make a thick paint. Apply with a brush in the ordinary manner.

It takes no extraordinary skill or practice to make and use any of the washes given in the above formulas. All the care that will be necessary will be to mix them carefully and apply in a workmanlike manner. In formulas 1 and 2, two ounces of strychnine may be added instead of the Paris green or arsenate of lead.—J. E. Mundell, New Mexico, Col. of Ag.

ENGLISH DEMAND FOR AMERICAN FRUIT.

The fruit crop this year probably will be the largest ever known in the history of the Niagara peninsula; and Niagara district fruit will be plentiful in the British market. One shipment will be a large consignment of apples and peaches. Another shipment of 675 cases of St. Catherines peaches will be sent to London, Liverpool and Glasgow. The fruit will be specially wraped in wool and will be packed in boxes.

A report was received at the Department of Agriculture, Toronto, from one of the largest commission houses in Great Britain, stating that the fruit crop there had been a failure, and figures received from all parts of the United Kingdom show that the apple-crop is the worst that has been known for many years.

The scarcity and damage are great and the crop almost a failure. The report states further that the British markets are ready to receive American and Canadian fruits when attainable. Early varieties, landing in good condition, should arrive at an exceptionally good market.

The total exports of apples from Canada in the fiscal year ending March 31, 1909, aggregated in value $2,804,282, representing 1,092,066 barrels. They all went to the United Kingdom except 19,233 barrels to the United States, 8,365 barrels to Newfoundland, 5,924 barrels to British Africa, 3,110 barrels to Cuba, and 7,069 barrels to all other parts of the world.

Canada also shipped in the same year $305,426 worth of dried apples, mostly to Holland, and $204,246 of canned or preserved fruit, almost all to Great Britain.—Counsul W. H. H. Webster, Niagara Falls, Canada.

CUTTING BACK OLD PEACHES.

After the lapse of three or four years, unless peach trees have been carefully pruned every year, they are generally of a straggling appearance, without bearing wood only at the extreme ends. This is not desirable, and with proper management need not be. However, when trees are in this condition they can be made as good as new by a good pruning when they are dormant, say toward the approach of spring. Saw them back to near the lower ends of the branches, when new shoots will follow, resulting in trees full of vigorous young shoots. When the cutting back of all that appear to require it would result in the loss of a crop the season approaching, there may be a compromise in pruning. Instead of cutting back all the limbs, take the worst only, letting the rest go until the year following. The appearance of the tree would not be as good as it would were all the limbs cut back at the same time, still the getting of fruit is of more consequence than the appearance, oftentimes. To prevent trees getting "long-legged," as gardeners call it, is easy. In summer, when the growth of shoots is being made, go over the trees, nipping off the ends of those that seem growing out of line. A pinching back of the shoots that need it causes the side buds to break the tree thus making a symmetrical tree and one from which the fruit is easily gathered. It is shaped in this way easier and quicker than when growth is let form as it will, trusting to the knife to set matters right later; and this applies to all trees as well as to peaches.—Practical Farmer.

ORCHARD WAGONS.

Don't overlook the vehicle that is to transport the fruit from the orchard to the packing house. This wagon should have low, broad wheels so arranged that they will cut under and permit a short turn. The low wagon can be driven through the orchard without rubbing the branches, fruit can be put on and unloaded without the back-breaking work that is required by the old high wheels. Bolster spring can be supplied, so that there will be no unnecessary jolting of the fruit in hauling to the packing house.

One type has a bed or platform that extends out over the wheels, and permits a larger load of fruit to be put on. See to it that there is a small strip nailed around the edge of the platform to prevent the boxes from sliding off in case there is an up or down-hill haul to the packing house.—Green's Fruit Grower.

Huntington Beach poultry raisers are planning for a poultry show.

TREES

Mr. Farmer

It's Raining

And the prospects are splendid for continued wet weather.

Perhaps you have been somewhat dubious over the weather prospects, but of course everything looks brighter to you now. Better see to your wants in trees, vines and the other things you intend to plant, and send your order along quickly. This wet weather is going to swamp us with business, and you had better take due notice and send us your order so that you can depend on getting just the stock you want to plant before the supply is exhausted.

Figs

Did it ever occur to you that of all the fruits planted there is none that will one year after another bring such sure returns as the fig orchard? Living under your own "Vine and Fig Tree" is one of the attractive similes of "California Horticultural Life." It is literally true with the fig, that the owner of this class of property has only to care for it during the winter months, for it is becoming a common practice in all the fig districts to sell the crops on the trees, while the trees are clothed in their winter garb, the buyers paying from one to two dollars per tree for the future crop, and assuming all responsibility for its maintenance, and for the harvesting of the crop. Doesn't this appeal to you, Mr. Fruit Grower?

If your land is all planted to other fruits, put in a border of fig trees; there is nothing like it for a permanent income. The failure of a fig crop in California is an unknown quantity.

We not only stand in the Lead as

headquarters for the growing of the CALIMYRNA FIG, but it is an actual fact, we have the largest stock on the Pacific Coast of Mission or California Black Figs, White Adriatic, White Endich, all of which are very profitable. We also carry numerous other varieties.

Let us figure with you

Peaches

During the season of 1909 and 1910 the Canneries here sold out their output at very remunerative prices. There has not been enough fruit to meet their demands and they are now entering into contracts on terms of ten years to guarantee a supply of fruit.

Can you afford to let an opportunity like this slip by when you can buy Peach Trees at lower prices than they have been offered for in past years? The stock we are offering for sale this season is not only more complete than it has ever been before, but our trees are better; have a fine root system simply because of the care we have exercised in growing them on selected soils, adapted to their most perfect development.

NO MATTER HOW SMALL OR LARGE YOUR ORDER MAY BE, IT WILL BE A PLEASURE FOR US TO FIGURE ON IT.

Illustrated Annual Price Catalogue

Just the book you have been looking for, because it briefly tells what the various fruits, as well as ornamental stock is like, and then gives you prices for them. Just drop a line today and secure this book, and begin lining up your order.

Popularity of Deciduous Fruit Varieties

The question of value of any variety of fruit for any section is best answered by trial of that fruit in the section. California has such diverse conditions, often but a few miles apart, that "a favorite in California" might yet be a complete failure in a particular locality of the state. However the general consideration of values may be profitable. The following list shows the estimate in which certain varieties are held by California growers and California nurserymen. by growers in Oregon, Washington, Utah and Idaho.

The list was originally compiled by Prof. E. J. Wickson, dean of the Agricultural College.

This list is valuable only in a general way and chiefly for the light it throws upon the trade in trees, although it will be found to have clear indications of important pomological inquiries to be subsequently taken up as to why certain varieties are high in one place and low in another. Some cases of this kind are easily explained, such as the precedence of American grapes over the vinifera varieties in the northern portions of the Coast, but even these vinifera varieties have a place, because some localities favor them. A more puzzling proposition is the popularity of the Moorpark apricot at the north. This variety stands even lower in California than the tables indicate, because of shy bearing; but in some interior regions at the north it is said to be more trustworthy, which may be explained by climatic conditions which give it more definite periods of dormancy and growth. This is a matter which is as yet purely conjectural and needs to be inquired into. There are many other similar studies to be made of the behavior of varieties of all fruits, both from cultural and commercial points of view.

Citrus Fruits.

In citrus fruits in California and Arizona, especially Southern California, the two leaders are the Washington Navel and Valencia, followed by the Thomson's Improved and the Mediterranean Sweet and St. Michaels. Commercially, the first two are far in the lead. In lemons, the Eureka stands first, with the Villa Franca and Lisbon contending for second place. The Mexican is the only lime grown in any appreciable quantity. In pomelos Marsh's Seedless stands first, closely followed by the Triumph and Imperial.

TREES

Walnuts

Perhaps you have never realized that for a permanent investment, there is nothing in the nut line more profitable than walnuts. Our supply includes all the leading types of California and French origin, in seedling trees, and also grafted trees on California Black Walnut root.

Pecans

For the great interior valleys—on damp alluvial lands, the PECAN undoubtedly holds the premium as a money-maker. The trees are not only beautiful ornamentals, strong growers, heavy producers, but they are also very profitable, the Paper-shell Pecans bringing no less than forty to fifty cents per pound. We grow an immense stock not only of the best seedling varieties, but also of the budded sorts like Stuart, Frotscner, Success. PLACE YOUR ORDER NOW BEFORE THE SUPPLY OF TREES IS EXHAUSTED.

True to Name

It is a great advantage to be able to get home-grown trees and vines, from a reliable concern, who use the greatest care and save no expense to supply their customers only healthy, clean stock "TRUE TO NAME." We have had wide experience in this business and thousands of satisfied customers all over the west can testify to our record for square dealing and superior stock.

Burbank Trees

Some of those new plums are without question the finest for table and shipping ever introduced. We cannot say too much in praise of the SANTA ROSA PLUM, and as to the FORMOSA, we are so enthusiastic over the future of this great plum, that it is no exaggeration to say it is not only a great grower, a wonderful producer, but it has fine size, exquisite cherry red color, most excellent flavor and aroma, as well as being a good keeper and shipper. Of all the plums in the market today, it stands out pre-eminently as the Drum Major.

You cannot afford, even if your space is limited, to miss this chance of securing a few of these trees at the exceptionally low prices we are offering them at this season. The New "STANDARD PRUNE" surpasses any drying prune we have ever seen, and unquestionably will rank in the lead of all varieties.

California Horticulture

To all practical fruit growers and horticulturists, our book, "CALIFORNIA HORTICULTURE—THE FRUIT GROWERS' GUIDE," is most valuable, containing concise and definite data for planting, pruning and care of stock, and in addition, describing the assortment of some two thousand varieties of trees and plants we handle. The price is only 25c postpaid, but worth many times this price in its wealth of Common Sense Information. To anyone referring to the name and date of this publication we agree to send a copy of this book without charge.

Garden and Field Crops

PLANTING POTATOES.

The natural home of the potato is the mountain valleys of South America. Where natural conditions are favorable for the growth of a plant, there it will reach the highest degree of perfection.

Preparation of the Soil.

In providing a suitable soil for potatoes, the question naturally arises, How shall we perfect and husband fertility? Live stock is the real basis of success in every agricultural district of the world. The feeding of grains and grasses on the farm replaces in the soil the vegetable matter which produces the humus and furnishes the nitrogen that keeps up the fertility of the soil. In the mountain country, where water is a prime requisite, it should be remembered that there is no better storage for water in the soil than decayed vegetable matter, and if one grows grain crops and ships them off every year, his land will become less porous and harder to work, and fungous diseases will find more readily a lodgment there. It is utterly impossible to grow good potatoes without an open, porous soil.

Nothing but the legumes—alfalfa or clover—should be used as a foundation crop.

Planting.

The writer plants the potatoes about two or two and one-half inches below the surface of the soil. Experiments with potatoes planted in rows all the way from thirty-six to forty-two inches apart indicate that the best distance depends upon the seasonal conditions and type of soil; it is a problem for each grower to solve for himself. The distance apart the potatoes should be planted in the row also depends so much upon the variety, the fertility of the soil, the availability of water, etc., that each farmer must determine this from his own experience. I plant them eight inches apart in rows thirty-six inches apart. This gives the largest tonnage of potatoes of desir able size.

Cutting Seed; Planting Whole.

The writer's experience has been that seed of large size (two to six ounce) produce strong, vigorous shoots, as they furnish an ample supply of plant food to sustain a strong and vigorous growth until the feeder roots can take up the food from the soil. An insufficient supply of plant food in the seed may cause the plant to become stunted before the root system becomes so developed that it can take up the plant food from the soil.

During the last two years the best results were obtained from planting medium-sized whole seed. While the cost of the seed has been considerably greater, the stand has been approximately perfect. Experience has proven that from one or two eyes only are sprouts developed in uncut seed. The seed end furnishes a strong vine; the other eyes usually remain dormant.

One of the greatest advantages of using whole seed is the protection from disease which may be present in the soil and which may attack the more tender exposed parts of the cut seed. The potato grower can ill afford to grow a crop of potatoes and lose from 20 to 40 per cent of a stand on account of using poor seed, or improperly cut seed, or seed of weak vitality. It is a matter of vital importance to get the plants started into strong, vigorous growth in order that they may better withstand adverse conditions later in the season.—Farmers Bulletin 386.

IRRIGATION OF POTATOES.

Generally speaking, irrigation water is cold, and it is highly important not to irrigate too frequently, since the water not only causes the soil to run together, but lowers the temperature to a point that is not favorable to the growth of potatoes. Irrigation water is applied only when the condition of the plants indicates that they are in need of water, as by darkening of the foliage. Or one may dig down in the hill and press a handful of soil in the hand; if it fails to retain its form, irrigation is needed. Care should be taken not to wait until the ground is too dry, because one cannot cover the whole field of potatoes in one day's irrigation, and some are likely to suffer for water before being reached. The writer's experience is that if potatoes are grown as rapidly as possible, so as to become strong and well established early in the season, they withstand the maximum of unfavorable weather conditions later on, when the hot, dry winds become a menace to the crop.

When the time for irrigation arrives, a V-shaped trench half-way between the rows should be opened in alternate middles, with an eight or ten-inch list plow; that is, a narrow plow with a double moldboard which throws the dirt each way. In these furrows the irrigation water is run so that the soil will not become solidified by flooding, and the necessary amount of water may be properly distributed. For the second irrigation furrows are opened in the middles that were not opened at the first irrigation, and this alternation is continued for succeeding irrigations. At the head of each field is a feeder ditch from which the water is admitted to these irrigation furrows between the rows. It is essential that the right quantity of water be used, and that it be uniformly distributed. Cultivation should commence as soon after irrigation as the soil will permit, so as to insure rapid and uniform growth without check. This will not only result in the production of smooth, uniform tubers of attractive appearance, which are always in demand at high prices, but will also result in large, profitable yields and at the same time keep the soil in good mechanical condition for future crops.

If great care and scientific methods are necessary for best results in the production of market potatoes, they are tenfold more important in growing seed stock for next year's planting. Uniform growth of tubers for seed purposes, without check in development, produces a seed potato of higher vitality than tubers of uneven growth; and the clean, smooth tuber with tough skin, free from clinging soil or dirt, keeps better and is freer from disease germs during the long season before next year's planting.—Farmers Bulletin 386.

Two tablespoonsful of molasses will help a spice cake to keep moist much longer. It should also be used in fruit cake, whether the recipe calls for it or not. Shutting it up in a tight tin box before it is quite cold will also keep a coffee or spice cake moist until it can be entirely used.

DISCOVERING A NEW CROP.

In Harper's for February, Professor Robert Kennedy Duncan tells how the great camphor industry has been recently revolutionized by a simple discovery. Heretofore the camphor had been extracted from the wood of the tree and its branches, thereby destroying the tree. Dr. Duncan, after visiting Jamaica, found a new method by which the tree is preserved and an annual crop guaranteed.

"In order to solve these questions I brought back with me to the University of Kansas nearly a ton of material, which we worked up to the last ounce. We extracted the best of the camphor and the oil of camphor from the wood of the trunk, from the branches, the twigs, the green leaves, the dry leaves, and the dead leaves, and we obtained results which afforded us profound astonishment and great joy. We thought we had made a great discovery, and as a matter of fact we had, though, unfortunately for us, these results had just been anticipated by the work of Messrs. Campbell and Eaton in Malaya, and by the director of the Biological Station at Amani, East Africa. Since, however, our results absolutely confirm the work of these gentlemen, and since they are so important to the whole great camphor-growing industry, I give them here. As a matter of fact, and speaking in averages, our results analyzed out as follows:

Wood	0.61% crude camphor
Twigs	1.05% crude camphor
Green leaves	2.37% crude camphor
Dried leaves	2.52% crude camphor
Dead leaves	1.39% crude camphor

"These results are extraordinarily high, owing partly to the fact that the material had undergone a considerable amount of drying in its long transport from Jamaica to Kansas, and partly, too, I believe, to the ideal conditions that obtained in Jamaica for the growth of essential oils. But it is the proportional amounts to which I draw attention. The wood of the camphor tree contains an insignificant fraction of the camphor contained in the green, dry and dead leaves. This is to be correlated with the indisputable facts, as proved by Mr. Malcolm of Jamaica and others the world over, that the leaves can be harvested regularly without any injury to the tree. These two facts, taken together, place both the huge camphor monopoly of Japan and its synthetic manufacture in Germany and elsewhere in a position that would be laughable were it not rather pitiful. Both types of organization proceeded on the assumption that the centuries-old traditional method of extraction was the only one. In order to continue it, the Japanese felled only trees fifty years old and extracted the drug from the wood only, leaving the leaves out of consideration. In order to carry out this destructive work, they ran deadly electric wires through the forests to keep out the savages, they placed armed men with every camp of camphor workers, and they paid these workers ninety cents a day for a native Formosan and $1.99 a day for a Japanese. The price of labor in Jamaica is a shilling a day for a Japanese. Now, as a matter of fact, in a five-year-old tree the mass of its leaves weighs 7.05 per cent of the total bulk of the tree. The proper method, therefore, without destruction of the tree, is to regularly harvest its leaves for their excessively large camphor content; costly expeditions into savage interiors and the total destruction of mature trees are wholly unnecessary."

THE COMPOST PILE.

Now is the time of year when the air is redolent with disagreeable odors and at times almost suffocating with smoke from burning leaves and rubbish in the streets and alleys near village and suburban homes. While this desire for neatness of surroundings is commendable the result may be accomplished with less time and labor and without the accompanying offensive smoke. There can also be secured a large amount of fertility for the gardens which should not be wasted. We highly esteem leaf mold and wood's earth from the forests, yet leaves and other surplus vegetation are but the material from which leaf mold is formed. An out of the way corner of the garden should be chosen where the leaves may be piled in a broad flat heap and held in place with a sprinkling of earth until the dampness of fall rains keeps them from blowing away.

A convenient receptacle for holding the leaves while being carried from the raking pile to the compost heap may be made from an ordinary bran sack such as can be purchased for a few cents at the seed stores. Cut the seams and spread the sheet of burlap on the ground and tack or sew a lath at each end. Better than laths, because stronger, are strips of hard wood or straight short poles from the woods. At the center of one end fasten a piece of rope and make a hole in the fabric next the middle of the other end. Place your carrier near the leaf pile, heap on it a sufficient quantity of leaves, then double the carrier around the leaf pile and secure the ends together with the rope. A grown person can carry all such a receptacle will hold or two children will find it light enough to handle.

Mighty stalks of cosmos, dahlias or other plants may be placed on top to keep the leaves from blowing away and add to the store of fertility. If it is convenient to pour house slops on the compost pile they will promote decay and add to the store of plant food. Soot from the stove pipe, feathers from dressing fowls, lawn clippings, surplus weeds from the garden, all should be given the pile in the summer to promote decay. If hot beds are in order on the place the spent heating material is another source of fertility for the home garden. And it would be worth while to have a hot bed because of the increased fertility made available where an ordinary manure pile would be considered a nuisance.

Because of the slower decay of the compost pile means of fertility are made available when the quickly heating manure pile could not be permitted.—Wisconsin Agriculturist.

Apples have been found to keep better if well colored and ripened, though not over-ripe. Picking should not be delayed till this fruit commences to fall.

Do not sell all the best. If anyone is entitled to the best fruit produced on the farm it is the home family.

W. A. T. STRATTON, Petaluma, Cal.

SUPPLY OF COTTON.

Census Bulletin 110 on the supply and distribution of cotton in the United States for the year ending August 31, 1910, will be issued in the near future by Census Director Durand. The statistics were collected and compiled under the supervision of Mr. William M. Steuart, chief statistician for manufacturers, assisted by Mr. Daniel C. Roper, expert special agent.

This annual bulletin forms the complement to the report on production, compiled from the returns of the ginners. It is the sixth of the series, and completes the statistics collected by the bureau relative to the cotton crop of 1909.

The supply of cotton in the United States for the year ending August 31, 1910, was 12,188,021 bales, a decrease of 20 per cent under the previous year, when the supply amounted to 15,312,885 bales. This decline apparently measures the difference between an adequate supply and one insufficient for the normal demand. The loss of 3,124,864 bales in the supply of cotton for 1910 is practically equal to the difference between the 1909 and 1908 cotton crops of the United States. Although the production of cotton in India last year was about 650,000 bales in excess of that of the previous year, nearly all of this increase was required to offset the loss in the crops of Egypt and of other foreign countries.

The Importation of Cotton.

The total quantity of cotton imported into the United States during the year ending August 31, 1910, amounted to 172,075 bales of 500 pounds each. Of this cotton the equivalent of 20,680 bales of 500 pounds each was re-exported, leaving in the country 151,395 bales, valued at about $15,500,000. This is an unimportant decrease in quantity of 14,056 bales compared with the number in 1909, and it is more than accounted for by the loss in the imports of Egyptian cotton.

Nearly all the cotton imported is Egyptian, used largely in the manufacture of thread, knit goods, and machine lace; and Peruvian, which is used as a substitute for wool in the manufacture of woolen goods. Recently a number of manufacturers have been experimenting with Chinese cotton in the manufacture of upholstering materials and in some instances in the manufacture of knit underwear. The direct importations from China for the cotton year 1910 amounted to 7,129 bales and the direct importations of Indian cotton, used, among other purposes, for mixing with the American fiber in the manufacture of cheaper grades of goods, amounted to 8,756 bales of 500 pounds each, a very large increase over any previous year.

Distribution of Cotton Supply.

Of the total supply of cotton for 1910, 4,808,953 bales, or 39 per cent, including that destroyed by fire, were consumed in this country; 6,339,028 bales, or 52 per cent, were exported, while 1,040,040 bales, or 9 per cent, remained in the country at the close of the year. Of the supply for the preceding year 34 per cent was consumed at home, 56 per cent was exported, and 10 per cent remained in this country.

The total consumption of cotton in the United States for the year covered by the report, including that destroyed by fire, was 446,323 bales less than during the year ending August 31, 1909.

The exports during the year were 2,234,996 bales less than for the previous year and were the smallest for any one of the last five years.

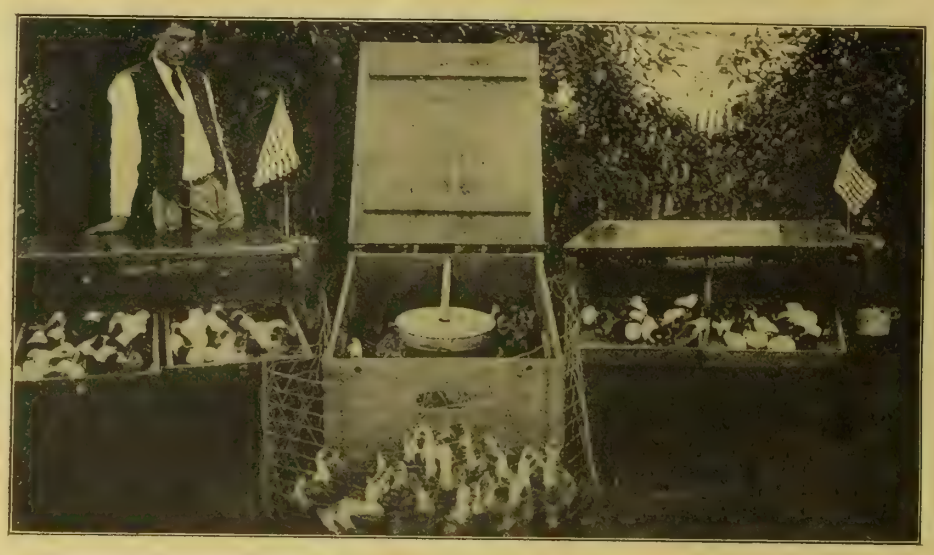
The stocks of cotton in this country at the close of August 31, 1910, amounted to only 1,040,040 bales, compared with 1,483,585 bales on the corresponding date of the preceding year. Those held by manufacturers in the cotton-growing states at the end of the year were 35 per cent less than in 1909, and by manufacturers in all other states, 43 per cent less. The quantity of stocks, 533,232 bales, held by all the manufacturers on August 31, 1910, was the smallest for any of the last five years and represents less than six weeks' supply for the American cotton mills operating under normal conditions.

The report states it is evident that the tendency in the United States is to employ ring rather than mule spindles, the latter forming but 17 per cent of the total number in 1910, as compared with 23 per cent in 1905, 29 per cent in 1900, and 38 per cent in 1890. About 77 per cent of all the mule spindles are in the New England states and most of the others are in New York and New Jersey.

The quantity of cotton consumed during the year ending August 31, 1910, was 4,798,953 bales, compared with 5,240,719 bales in 1909, a decrease of 441,766 bales, or 8 per cent. The average weekly consumption of cotton in the United States in 1910 amounted to about 92,000 bales, compared with 108,000 in 1909, 97,000 in 1908 and 96,000 in 1907.

This is a photo of Victor Smith, of Creswell, Oregon, and his two "Success" Incubators, and brooder. Note the nursery full of chicks, brooder full of three-weeks-old turkeys, brooder yard full of month-old Indian Runner ducklings. Success Incubators will hatch all kinds of eggs. No guesswork.

(Since this picture Mr. Smith moved to Santa Cruz, Cal., 16 Towne avenue.)



This man hatched 2,415 chicks between December 1, 1909, and July 1, 1910.

Mr. McClanahan. Creswell, Oregon, July 11, 1910.

Dear Sir: With these two machines I hatched 2,415 strong, lively chicks between December 1, 1909, and July 1, 1910. After giving your machines a thorough test alongside of other incubators, I am satisfied that the Success machine is one of the best hatchers on the market today. I will probably place an order for six more of the large machines for this coming year. Our hatches averaged well every month, which shows your machine can be depended on at any time of the year. The brooder has proven satisfactory in every way.

VICTOR SMITH.

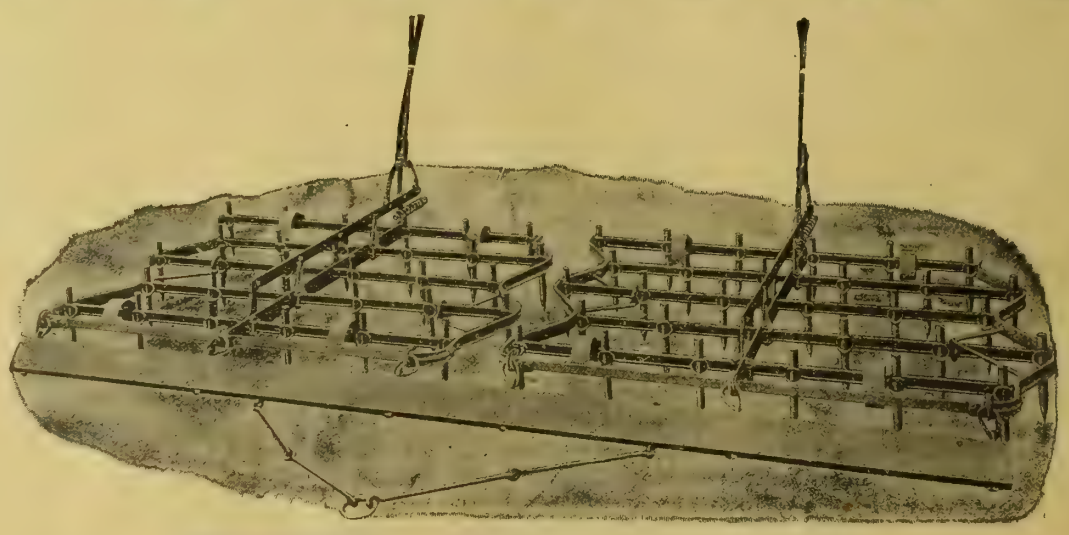
HARROWS



NO. 3 SUNSHINE U BAR SPIKE TOOTH DRAG HARROW

There will be more happiness in this world when every ranch has a Sunshine Drag Harrow—the best made.

No. 3 Sunshine Drag Harrows are strong, staunch, and reliable.

The teeth are fastened by wide mouth clips to special heavy rolled U Bars.

Strain and consequent wear are almost wholly removed from the frame by a steel strap across the front of each section, and a strap connected to the draw bar which runs from front to rear of each section, and through which each U bar runs. Two half-inch wrought iron—not malleable—braces are used on each section. The teeth may be set at eighteen different angles, sufficient for every kind of work. The Strap Ratchets and Lever connections are very strong.

The No. 3 is a perfect field harrow and most useful in orchard work. The Side Guards prevent injury to trees, and the Bent Levers will not catch limbs.

Remember that some harrows are poorly constructed—not necessarily cheap—and are a source of endless trouble.

Sunshine, Spike Tooth, Spring Tooth, Single and Double Disc Harrows, made in large variety for Field and Orchard use. Write for full particulars.

Dairymen and stockmen are requested to write of their experience. Mrs. Sherman is always willing to answer queries and this, with experience of other workers, will make this department of greater value.

MIXED RANCHING.

By Mrs. M. E. Sherman.

When one stays at home constantly he loses sight of the wonderful development by the new settler going on in all parts of California. Everywhere the country is coming under cultivation, almost by magic, it seems. One year a grain field of uncultivated land, the next year a few shacks appear, and in five years the palms are growing, the orchards are there, with alfalfa, and, best of all, the pretty cottage home, and near by the stately school house. The school houses in many of the tiny towns are fine structures of brick, concrete or stone, with considerable architectural beauty. The interest in dairying and swine raising is intense among the newer arrivals. They feel that cows and hogs are something they understand better than the California ways of growing fruits. It shows conservative wisdom to follow the known lines in securing a living. These men often say to me: "I know I can make a living at that, and next year I will plant an orchard, for then I will have had time to understand better what to do with it." On the last run of the demonstration train we went to Colfax and the intervening towns, then to Placerville, and then to Milton, and then down the San Joaquin valley as far as Merced, stopping at the smaller places between these main points.

After the crowds going through the train had passed, there were always a few that lingered to talk live stock. It is often amusing to see the disgust of some of the Cultivator readers when they find I am a horticulturalist and viticulturist instead of a live stock demonstrator on the train. It seems to be a California idea of ranching that one must grow only one thing, instead of having a ranch of varied industries. The three hundred acres of vineyards and the olive orchards are as important financially to the ranch as the cows, horses and pigs. The ranch is balanced, and something is always paying good returns. The products of vineyards and orchards are gradually being renewed as the older plantings grow less productive, by planting the alfalfa lands to trees and vines. The land in trees and vines for twenty-five years is being turned gradually into alfalfa fields. It is a rotation, a very long one, that is in use on the older ranches. Thirty acres of vines, twenty acres of trees and fifty arces of alfalfa will make the new planting this season. After the fourth year the orchard and vineyard will become profitable, while the alfalfa is profitable the first season.

The cows and horses follow the law of nature to multiply and increase their kind. This season the forty cows have raised forty-five calves from December 1, 1909, to December 1, 1910. There are few years in which they do not do as well. Ten sows last spring gave eighty-six pigs that reached a hundred or more pounds in weight before being sold. Fifteen sows this fall have dropped one hundred and twenty-three pigs, now weighing from forty to sixty pounds each. These increases are not given as anything wonderful, but to show what results of healthy stock, raised out of doors with sufficient food, will do on the regular ranch. One mistake that ranchers all make is not feeding regularly. If feed is scarce, always sell the stock, and give to those retained enough to keep them growing. Do not try to stretch the feed to keep a larger number merely alive. In the first place, it is cruel to have animals having less food than they need. In the second place, it is not economical to stunt an animal, particularly a young one, for it never fully recovers, even with additional feeding and care, the growth lost before maturity.

In mixed farming there are no seasons of rest. The raisin growers go for a month to the seaside, while the dairyman must stay with the cows. The green grape grower has a long rest between the time of Malaga shipping and the late Emperor season. Yet the live stock belongs with the orchard and vineyard as a source of fertility. The orchard trees are stronger and the crops heavier when well fertilized. The bills for grain to feed the live stock take the place of the bills for commercial fertilizers. The need of humus is met in a measure by the strawy manure, while the nitrogen is at once available in the liquid secretions that are carefully saved for the land. The manure spread in the orchards during the summer starts into growth from the seeds in it at the first rains. If a few pounds of burr clover or of common field peas are mixed in with every load, a great mass of green is grown without any cost of sowing. This humus is needed in all the soils even more than all else—for, as Dr. Shaw says, "it is the minus quantity."

In selling butter fat from the cows one is not selling the fertility of the soil as he does when he sells hay or milk. The feeding of hay at home to cattle increases the manure available very greatly. The corrals can be scraped and regraveled or sanded cheaply. The scrapings go out to the fields as readily available plant food. The man at the head of the dairy is, after all, the important person in determining the actual success or failure of the cows as butter makers. Careful handling and plentiful feeding make it possible to develop all there is in a cow as a butter producer. The people are slow to grasp the idea that the best bred cows as butter producers are as surely man-made as an automobile. The constant selecting of the best cows ages ago resulted in the formation of different breeds. Then man got busy and said, "Let us make herd books." These herd books took in the cows of one country, usually those that had made so much butter or given so much milk. Then, after ten years, only cows that had dams and sires in the herd book were eligible for registration. Then certain forms and markings were considered as desirable. After a time, within the breeds, grew up certain strains that were considered superior. Then came the testing of the cows as butter makers, first at fairs, then by owners, and finally by the officials of the experiment stations making what have been known as official tests. These tests are recorded in the society and

association herd books, and are now the standard of performance. Like tuberculin testing, they are soon likely to become almost imperative in the securing of good prices for cattle.—M. E. Sherman.

BEEF CLUBS.

By Charles Dillon, Kansas State Agricultural College.

The farmers of Kansas, one of the first live stock states in the Union, buy from the butcher shops, annually, from three and one-half million to seven million dollars worth of meat. They produce this meat themselves. It consists, chiefly, of breakfast bacon, ham, salt pork and fresh beef. These meats will retail at from 35 to 40 per cent more than they cost wholesale at the packing houses, if the figures of Secretary Wilson are correct. It is safe to say that, allowing for transportation from the farm to the packing house, the killing, selling, etc., these meats, when returned to the farmer through the retailer, are bought by him at an increase of at least 50 per cent.

In doing this they contribute to the profits of the other man one-half the value of the stuff they themselves produce.

Beef Clubs Needed.

The foregoing somewhat startling facts were part of a carefully prepared address delivered a few days ago by Henry J. Waters, president of the Kansas State Agricultural College, speaking to the Improved Live Stock Breeders Association at Topeka. The title of this address was "The American Farmer as a Meat Packer." President Waters told the interesting answers from a series of questions he had sent to all the farmers in Kansas, in every one of its 105 counties. The replies came from 97 counties.

Summarized, they show that very few farmers cure all the meat that can be cured for their use; that there is very little co-operation in killing, as might be the case if beef clubs were organized. It is the common practice, these statistics show, to depend upon the butcher shops and farm poultry for meat in from six to nine months of the year. Estimates as to the meat bought by the average farm family of five persons varied from $10 to $300 a year. The average was $55. This would make the Kansas farmers' total meat bill $7,335,000 a year; enough to support the state government and the schools for two years.

Why have the farmers ceased to cure meat for themselves? President Waters inquired. Being an expert in this work himself, and believing in imparting the knowledge of it to others, President Waters was more than ordinarily concerned. In former years, he said, when the farm was more nearly the center of family life, when the family lived more completely upon the produce of the farm and less upon breakfast foods and canned goods, it was the practice to cure all the meats required by the family for the year, except that from poultry. Beef clubs co-operated in such work. But the increased prosperity of the farmer and the recent high prices of animals on the hoof have permitted the meat-curing industry to become almost a lost art.

Not Much Equipment Needed.

President Waters' first questions to the farmers brought out the answer, generally, that they did not know how to cure meat. The second largest number told of the lack of necessary facilities, smoke house, etc.; some reported that the meat spoiled, another way of confessing ignorance of how to cure it. Others said insects interfered with its keeping, another detail of knowing how; it became too salty and unpalatable; it was strong in the summer; all confessions of ignorance.

What They Miss.

President Waters declared it was a mistaken idea that an elaborate equipment was necessary in curing meat. A wooden smoke house with earth floor would answer every purpose, and the profit paid to the packing house and the butcher shop for one year, on the basis of $55, would buy all the equipment needed by any farmer, although not the best or most convenient. Killing should be done by the end of January, and for best results by Christmas time. This will allow time to cure and smoke the meat and put it away before the arrival of the flies which produce the skippers about which so many farmers complain. You should have a March or April hog weighing 200 to 225 pounds. The curing is a matter of personal detail and attention, President Waters says. There are a great many ways to produce ham or bacon with very superior flavor. One of the first essentials is plenty of time.

The reason the packing house ham is so lacking in flavor is that it is cured rapidly and quickly sold. There

Do your cows milk hard? Send .50 cents for teat expander. O. J. Weber Co., 225-227-229-231 East Sixth St., Los Angeles.

are two methods in curing meat, the dry cure and the brine cure. Both are good. The meat curer should take the one he happens to fancy, but for production of the highest quality and richest flavor the dry cure is superior. Brine destroys a considerable quantity of the soluble protein in meat, and that is what gives the flavor. Any piece of meat soaked, or even wet, is never again as good as it was.

There is no just right and no just wrong way in curing meats. It is largely a matter of taste and judgment.

Here Is the Approved Dry Cure.

To 1,000 pounds of meat take the following:

40 pounds common salt.
10 pounds New Orleans sugar.
4 pounds black pepper.
1½ pounds salt petre.
½ pound cayenne pepper.

Weigh the meat, and take such part of the ingredients as that is a part of the 1,000.

Let the meat cool thoroughly. After thoroughly mixing the ingredients, one-half of the amount should be rubbed well into the meat. Put the meat in a dry, cool place (never in a cellar). Let it remain two weeks, then rub on the remainder of the cure, and let it lie about six weeks, when it is ready to hang. Smoking should be done slowly. It should occupy four to six weeks, a little every day, and with little heat. Slow smoking gives a delicate flavor. After the smoking is finished, wrap each piece in paper, put in an unwashed flour sack and hang in a dry place.

The brine cure requires the same materials minus the pepper. When the meat has cooled, rub it with salt and let it drain over night. Pack in a clean barrel, with the heavy pieces, hams and shoulders, at the bottom. For every 100 pounds use 8 pounds of salt, 2 pounds brown sugar and 2 ounces salt petre. Dissolve in four gallons of water and cover the meat with it. Thin sides should remain in this four to six weeks, and hams six to eight weeks. After it has dried thoroughly, smoke as in the dry cure.

Here are a few figures showing what should be procured from a 250-pound hog:

35 pounds ham @ 17c	$5.95
30 pounds shoulder @ 10c	3.00
25 pounds thick sides @ 10c	2.50
21 pounds thin sides @ 20c	4.20
30 pounds lard @ 15c	4.50
40 pounds spare ribs, head, feet, backbone @ 7c	2.80
18 pounds sausage @ 20c	3.60
	$26.55

The hog was worth at home $18.10. Had the meat been cured there, the farmer would have cleared the ham at reasonable prices—$5.95—and almost the hams and shoulders, or about 40 per cent profit. The weights quoted here are green weights. The joints will increase in salt and decrease in smoke, so it is about an even break by the middle of the summer.

DRYING OFF THE COW.

In drying up cows, one "iron-clad rule" may not be just the thing for all breeds of cows. Nature would not, of course, cause the secretion of milk to stop immediately. So we must get down to nature in this as near as we can. So should it be in all dealings with our domesticated animals.

Now in drying up a cow, a few questions may be asked. What causes a good flow of milk? You answer: (1) Good succulent foods; (2) an abundance of pure water is also a necessity. However, it must not be inferred that these must be discontinued. They should be reduced in bulk. So much for feeding.

In milking, the attendant should know how much milk the cow has been giving at each milking. Three-fourths should be milked out, the remaining one-fourth allowed to remain in the udder. In a short time milk out still less. Then make the milkings farther apart, and so on, until the cow no longer secretes milk. It must be understood that the gradual scale is the one to use. No abrupt methods should be used.

No specified time as to how long between milkings can be offered, from the fact that no two cows are the same. One is a heavier, the other a lighter milker. One is easy to dry up without any danger of injury to her udder—the other cow is just the opposite. The dairyman knows each individual cow in these respects, and consequently only his good judgment can be followed here.—Jersey Bulletin.

Anthrax Cure, Milk Fever Outfits. See O. J. Weber Co., 225-227-229-231 East Sixth Street, Los Angeles.

Genuine and Imitation CREAM SEPARATORS

The all-around superiority of the DE LAVAL Cream Separators, in farm as well as factory sizes, has now become so generally recognized that would-be competitors have, almost without exception, adopted the pretext of merely claiming that the machines they offer are "like the DE LAVAL", or "as good as the DE LAVAL", while some even go so far as to claim that their machines are made under a patent license from the DE LAVAL Company.

All of these claims and pretenses are false and a fraud upon the buyers of such machines, except to the extent that each and everyone of these would-be DE LAVAL imitators is using some ten to twenty-year-old patent expired and now abandoned type of DE LAVAL construction, though lacking all the essential elements of the improved DE LAVAL machines of today, or for that matter the DE LAVAL machines of the past five years, while none of them do or can use the still patent protected "split-wing" distributing shaft feature of all DE LAVAL machines since 1900.

Buyers of separators are cautioned against such deceptive misrepresentations by those who may try to induce them to purchase machines claimed to be similar to the DE LAVAL, but which in no way compare in efficiency, capacity or general practicability with the DE LAVAL machines of TODAY.

DE LAVAL Cream Separators are as much in advance of all attempted competition today as at any past time, and their use is speedily becoming as universal on the farm as it has long since been in the larger sizes in creameries and milk stations the world over.

THE DE LAVAL DAIRY SUPPLY COMPANY

165-167 Broadway, NEW YORK

The 1911 United States Separator

A MARVEL OF EASY RUNNING

There have been tremendous advances in the running qualities of the United States Cream Separators.

The skimming power is there. The same that won the world's record in fifty consecutive tests extending over a period of thirty days with the milk of ten different breeds of cows. .0138 of one per cent.

BUT—with the new Interlocking skimming device, the centrifugal action on the milk is so **intensified,** the course along which the milk is forced to travel so **lengthened,** the skimming force so **increased,** that the Interlocking bowl for any given capacity is reduced nearly **one-half** and runs with about **half** the **power** required for older models.

Now add to this great improvement the fact that the United States Separator is the only successful separator that distributes the incoming volume of the whole milk **evenly outside the cream zone,** thus preventing any remixing of cream and skim-milk, and you will see why it is that the Interlocking Style U. S. Separator is gradually displacing every other separator on the market.

A free demonstration will be given by selling agents who are located in nearly all dairy sections of the country. Ask for catalogue 20 today and we will give you agent's name.

VERMONT FARM MACHINE CO., BELLOWS FALLS, VERMONT.

Warranted to Give Satisfaction.

Gombault's® Caustic Balsam

Has Imitators But No Competitors.

A Safe, Speedy and Positive Cure for Curb, Splint, Sweeny, Capped Hock, Strained Tendons, Founder, Wind Puffs, and all lameness from Spavin, Ringbone and other bony tumors. Cures all skin diseases or Parasites, Thrush, Diphtheria. Removes all Bunches from Horses or Cattle.

As a Human Remedy for Rheumatism, Sprains, Sore Throat, etc., it is invaluable. Every bottle of Caustic Balsam sold is Warranted to give satisfaction. Price $1.50 per bottle. Sold by druggists, or sent by express, charges paid, with full directions for its use. ☞Send for descriptive circulars, testimonials, etc. Address

CONTENTS THIS WEEK

STANDARD BRED BROWN LEGHORN, Cover.

CITRUS PROTECTIVE LEAGUE, 131.

CITRUS AND TROPICAL FRUITS.—Cherimoya; How Frost Is Formed; A Gamble; Old Machinery: 132, 133.

DECIDUOUS FRUITS.—Preventing Injury to Young Trees by Rabbits; English Demand for American Fruits; Cutting Back Peaches; Orchard Wagons; Popularity of Deciduous Fruit Varieties: 134, 135.

GARDEN AND FIELD CROPS.—Planting Potatoes; Irrigation of Potatoes: 136.

HOME GROUNDS BEAUTIFUL.—Discovering a New Crop; The Compost Pile: 137.

GENERAL AGRICULTURE.—Supply of Cotton: 138.

LIVE STOCK AND DAIRY.—Mixed Ranching; Beef Clubs; Drying Off the Cow: 139, 140, 141.

EDITORIAL.—Fence Law; A Hummer; More Water; Irrigation; The New Standard; Organizing Apricot Growers; Financing the University: 142.

AGRICULTURAL NEWS NOTES OF THE PACIFIC COAST.—Northern, Central, Southern, The Coast: 143.

PRACTICAL POULTRY CULTURE.—Breeding and Feeding of Ducks; Abundance of Good Things: 144, 145, 146.

TIMELY RANCH SUGGESTIONS.—Population and Subsistence; Pocket Gophers; Simplicity; Cost of Flies; Careless Farmers: 147, 148, 149.

QUESTIONS AND ANSWERS.—Pruning Apples and Pears; Trapnests; Miner's Inch; Ferrets; Scabby Potatoes; Peaches Out of Condition; Slow Moulting; Seville Oranges; Scaly Leg; Black Leghorns; Gophers; Ginseng; Removing Trees; Avocado; Grafting Walnuts: 151. Trees; Avocado.

VETERINARY.—Lameness; Abnormal Appetite: 151.

IRRIGATION AND FORESTRY.—Winter Irrigation of Orchards; Danger to All Interests; Land Sharks; Power Permits; Prospects Better for Irrigation Bond Issues; To Be Reclaimed: 152, 153.

HOUSEHOLD.—As You Make It; Story of Rameses; Drief Beef: 155, 156.

PRODUCE MARKET.—Los Angeles Market, San Francisco Market; Deciduous Market; Citrus Market: 158, 159.

FENCE LAW.

We referred in last week's Cultivator to the peculiar law regarding fencing against stock, and stated that to secure damages against owner of trespassing stock, it was necessary to have good substantial fences around premises. This condition is entirely contrary to the general idea though the law has been in force for the past four years. After looking up the question, Mr. Payne who answers legal questions for Cultivator readers, says:

"The Act of March 23rd, 1907, to be found in the Statutes and Amendments of that year, p. 999, gives a right of action for damages by any animal 'which breaks in and enters upon any land owned by or lawfully in the possession of any person, firm or corporation, other than the owner of vines, fruit trees or vegetables, and is, at the time, entirely inclosed by a substantial fence or other inclosure.'

"It has been decided by our Supreme Court in the case of Merritt vs. Hill, 104 Cal., 184, approved in Wigmore vs. Buell, 122 Cal., 150, that there is in this state no common law right in the owners of land to recover for the trespassing of animals on their land.

"I therefore conclude that no damages can be recovered for trespass committed by animals, except under the statute of 1907, as that law repealed prior statutes giving right of action for damages, and therefore no damages can be recovered unless the land is fenced or enclosed, as provided by that statute. Such a state of affairs is certainly outrageous, and calls for remedial legislation.

"The statute of 1907 ought to be repealed and a law enacted giving damages actually sustained by the owner or possessor of any land from trespassing animals regardless of any question of fence."

The Antelope Valley Ledger says that residents in that section are thoroughly aroused over this fence law and have sent many protests to senators and assemblymen at Sacramento. We do not believe the better element among the stockmen in the state would ask for any law which would compel the grower of crops to fence against his stock.

A HUMMER.

Did our readers notice last week's Cultivator? It was full from cover to cover of valuable material. Of course this one issue was largely given over to the poultry industry, but much of the material was not only original, but fresh and crisp and very valuable to the poultry raiser. Another issue which will center largely upon one line of California's industries will be that of February 22nd which will be given over almost entirely to citrus conditions in this state. Some of our brightest fruit growers have written of their willingness to join in this issue, and we will give the value of a year's cost of The Cultivator to the citrus grower in that one issue.

Speaking along another line, may we refer to the advertising pages of the same issue. Sixty-seven columns of announcements, 217 separate ads, of things of interest to fruit grower and farmer. That feature itself makes the Cultivator of great value to the farmer who would be up-to-date. Too many readers consider the space given to advertising in a paper as to a certain extent lost from a cultural standpoint, but we do not think the up-to-date farmer would for a moment part with the announcements which our advertisers give. The advertiser is almost invariably the handler of things which make for success in agriculture. The intensity of competition necessitates every soil tiller producing at the very lowest. This can only be done by keeping up-to-date and that means keeping in touch with the modern advertiser. Our little liner page alone exceeded its greatest limit. In fact, instead of being a liner page, it was a page and a quarter of agate type. The Cultivator takes just pride in this manifestation of its popularity with reader and advertiser.

MORE WATER.

The people of Covina are looking to a larger and more permanent supply of water by damming a section of San Gabriel Canyon. Their water supply is good, but they wish it to be better. This is the part of wisdom notwithstanding the extravagant claims made for dry farming. One writer in Los Angeles has made the statement that it is possible to secure crops of grass or grain with three and a half inches of rainfall. This writer is apparently talking of something which he knows nothing about, for no crop was ever produced with such rainfall. Of course dry farming methods used in California are beneficial in the conservation of water, but we cannot conserve that which we have not. As we heard C. C. Chapman of Fullerton remark recently, "I cannot afford to grow oranges on high-priced land without abundance of water and fertilizer." Agriculturally, our state is great and has been made so by irrigation. The counties which have shown the greatest growth are those which have given the most attention to the development of water. Too much of our wealth has been allowed to waste away to the ocean at time of winter floods. Let every possible means of impounding these waters be developed.

IRRIGATION.

One citrus grower of Riverside county reported to the Cultivator recently that the past year showed twelve irrigations of his lemon orchard. Furthermore, the coming year, no matter how much it rained, would see the same number. His idea is that during the winter season every bit of water which can be stored in the soil and subsoil should be conserved in that way. Formerly fruit growers felt that irrigation for the season should terminate by the first of October, or, under unsatisfactory conditions, not later than November. If we get a heavy rainfall such treatment of the trees will produce no ill effects, and it is the cheapest insurance to fill the soil with water.

THE NEW STANDARD.

Mail and telegraphic advices give The Cultivator to understand that at about the time this issue is passing through the press, the new revised Standard should be on sale at the supply houses in Los Angeles. Needless to add that everyone having to do with pure-blooded fowl should be in possession of a copy and learn its requirements. This edition contains much new matter, gives correct colored plates of the plumage of different breeds and varieties, disqualifications of all recognized breeds, instructions to judges, and half-tone plates of all the breeds recognized by the American Poultry Association. If you are in the game either along utility or fancy lines, you will find the book useful in developing your business. Yes, indeed.

ORGANIZING APRICOT GROWERS.

The success of the Orange County Dried Fruit Association during the past season has put that organization on its feet so that it is now trying to perfect an organization of all apricot growers of the state. Mr. J. G. Berneike, of Santa Ana, largely responsible for the formation of the Orange county growers, is sending out a circular of which the following is the principal part of text. A special effort is being made to get Santa Clara county organized. That is the largest producing section in the state. The success of the Orange county organization is evident when it is understood that ten cents was practically the minimum price received for last season's dried cots while some sections took as low as six and one-half and eight cents. We believe that if growers will join in the movement started by the Orange county association they will save thousands of dollars.

From Mr. Berneike's circular we quote:

"Are you interested in forming an apricot growers association? If so I would like to correspond further with you. Our association was organized before last year's crop, but too late to put in a packing plant, yet we were eminently successful. We have over 100 members, sold our fruit at a minimum of ten cents, and are still holding about seven carloads for eleven cents. Some is moving now at that figure. We are now getting ready with a packing plant for the coming crop, and shall add a pit-cracking plant as soon as possible. Ventura county has organized. They got ten cents and better and are now holding 9 to 10 cars for twelve cents."

FINANCING THE UNIVERSITY.

It is reported that several lobbyists of the state university are in Sacramento looking after the interests of that great institution. Possibly this is necessary, but for an institution of that kind it is most regrettable. The funds to support these men in their lobbying work come from some source and presumably from the treasury of the university from money appropriated for purposes of education. This is a use not contemplated in the appropriation. If the people are not awake to the needs of the institution, this is not the proper means for awakening interest. Let our state legislature be generous with the university; let not the university educate the people of the state in this kind of political work.

Fresh fruit handlers the state over are alarmed at the effort in the state legislature to pass an eight-hour law for labor in orchards, canneries and dry-yards of the state. With the shortage of labor that obtains at fruit curing time, such a law would mean untold loss. It is hoped that our legislators will apreciate California's greatest industry's needs to the extent of suppressing this bill.

The people of San Bernardino are planning for a National Orange Show to be pulled off in that city March 6 to 11. $4000 for expenses and premiums has been raised. Features of the show will be free distribution of oranges and a general boost for the greatest fresh fruit industry of the state.

Tree Warden Reed of Riverside county asserts that attractive street trees are the greatest factors in adding value to rural property.

Agricultural News Notes of the Pacific Coast

Northern California

The Davis almond growers association has just sent its last car of almonds.

A farmers telephone line is being constructed near Paradise, Butte county.

Pomona Grange of Sonoma county met in Santa Rosa last week in all-day session.

A Niles poultryman has just made a shipment of 100 White Leghorn pullets to Honolulu.

The Live Oak almond growers association shipped a car of almonds last week, netting $2500.

One rancher of Germantown, Glenn county, has sixteen pumping plants on his 640 acres of land.

Representatives of the state board of health have been investigating conditions in the dairies at Chico.

It is reported that eucalyptus men are endeavoring to secure a successor to G. M. Homans, state forester.

A number of dairymen along the Eel river near Ferndale, Humboldt county, are installing a telephone system.

Large numbers of "market hunters" are securing and shipping great quantities of ducks from Sutter county.

Bishop Bros. of San Ramon, Contra Costa county, have just made extensive purchases of pure bred Shropshires.

Cloverdale people will give more attention to their citrus fair and expect a bigger success than from any former event.

Timber men near Redding, Shasta county, are doing winter burning in the forests to lessen the danger of summer fires.

The Farmers Union of Gridley recently installed officers, W. F. Randolph being president and George Larson, secretary.

Twenty-five thousand acres of land near Lowery, Tehama county, will soon be under irrigation with waters from Elder Creek.

Speaking of drouth, a good place to grow things should be at Branscomb, Mendocino county, where they have an average annual precipitation of about eight feet. On a favorable year like 1903-4 the precipitation was 132.62 inches, or over 11 feet.

The report that the assemblyman elected from Sonoma county was working for a bill in effect that it should be a misdemeanor for any dealer to offer more for white eggs than for brown, is a fake. At least so declares the aforementioned assemblyman.

The California Creamery Operators Association is fathering a bill introduced in the legislature which will fix a license on the manufacture of oleomargarine at $300 per year and a license of $200 a year on wholesalers and importers. Retailers must pay $50.

The Sebastopol Berry Growers' Association recently elected its old board of directors as follows: W. I. Newcomb, W. H. Hotle, J. R. Rosie, J. P. Carvalho, Mrs. L. E. Barlow, D. D. Sinclair and F. F. Clayton, and the officers selected are: I. Newcomb, president; J. R. Rosie, secretary, and I. N. Cable, manager.

Central California

The gradual increase in the price of barley is gratifying to grain producers.

Vineyard pruners in Fresno county are concerned over the shortage of labor.

Visalia is still working for its large pavilion to be ready for future citrus and other exhibitions.

For the first time in months water is running in the People's Ditch in Hanford, Kings county.

The Pajaro Valley is extending its apple planting more than at any other season for several years.

Orange trees are selling in Tulare county at about $1.00 each in lots of 1000 for five-eighths stock.

Owing to the few prunes being offered, market is firm and holders not at all anxious to make sales.

The veterinarian of Santa Cruz county reports dairies about Watsonville in the best condition ever.

Some fruit growers of the Santa Clara Valley are replacing their orchards with alfalfa and dairies.

Big orchards of Merced county have been proving profitable and extension of plantings will be made this season.

Raisin men of Fresno held a meeting last Friday to discuss the question of a boosting campaign for another Raisin Day.

The big sugar factory at Spreckels has just put on 100 additional machine repairers to overhaul the factory for next season.

Ranchers in the southern part of Monterey county along the Salinas river are getting excellent results from pumping plants.

A petition is to be presented to the board of supervisors of San Joaquin county asking that a reward be offered for coyote scalps.

Orange trees in carload lots are arriving at Porterville and other Tulare county points. The planting will be heavier than any former season.

A system of canals through the San Joaquin Valley is being discussed more seriously, not only the one coming close to Fresno, but several others are now being outlined.

A Chinaman who has made a fortune in packing salmon in Alaska has purchased a seventy-acre tract near Terra Bella and will plant it all to oranges.

The charges of graft in the Tulare county horticultural commission work seem to be simmering down to a feeling on the part of the board of supervisors that the horticultural commission's power was too great.

Watsonville hollers very loud because the latest boosting pamphlet issued by the Southern Pacific leaves Watsonville entirely off the map, while other towns much smaller are given in big type. Watsonville pays the Southern Pacific on one item, the apple crop, nearly $2,000,000 annually.

A Salinas valley cattleman is calling attention to the fact that while prime steers are quoted in San Francisco at 5¾ cents, the trade quotations were full loins 14 to 14½, short loins, 8 to 20, full ribs 10½, rounds 9 to 9½, and other prices in proportion. This gives the meat dealer an opportunity to make immense profit.

Southern California

Citrus sections report white frosts but nothing of a damaging nature.

The creamery at San Luis Rey, San Diego, received 3,600,000 pounds of milk last year.

A beet sugar factory with a capacity of 500 tons is to be erected at Perris, Riverside county.

A drainage district has been formed to reclaim 3000 acres near old Newport, Orange county.

The Imperial Valley has already turned out something in excess of 4000 bales of cotton.

Tustin, Orange county, asserts its importance as a bean producer by showing a $400,000 crop last year.

The gentle showers which have fallen over Southern California have started all kinds of ranch work.

J. W. George, one of the largest beekeepers of Imperial county, has declined the appointment of bee inspector.

El Centro creameries produced and shipped during the month of December 200,000 pounds of high-grade butter.

The Imperial Valley Oil and Cotton Company seems to have difficulty in financing and establishing its oil mill at El Centro.

Grape growers of Escondido, San Diego county, have agreed to co-operate in the pre-cooling and shipment of grapes next season.

The superintendent in charge of the viticultural experiment station near Brawley, is preparing ten acres for experimental planting this spring.

Settlers near the Mojave river are agitating for conservation of waters of that river and urging the reclamation service to take up the matter.

Many seedling walnut orchards will be grafted over to the more desirable varieties of blight resistants this season.

The celery industry of Orange county is about 20 years old and has reached the magnitude of about 3000 carloads annually.

The foothills above Yorba, Orange county, are proving a good section for the production of Bermuda onions for the early spring trade.

Ventura apricot trees are already coming into bloom. If given a favorable season, these blossoms may give some remarkably early fruit.

The planting of cotton in Imperial Valley this spring will be heavier than ever. Many of the growers are combining to secure seed of improved varieties.

With C. C. Chapman as president and G. Harold Powell as secretary, the Citrus Protective League promises to be of great value to the citrus interests of California.

A Fullerton orange grower claims some damage is being done by the orange worm. This worm has been in California many years and is not thought to be a menace.

The Limoneira lemon ranch at Santa Paula has always affiliated with the Southern California Fruit Exchange, but not until this season has it placed its entire marketing operations with that organization.

The Coast

The gate receipts at the recent Spokane poultry show were $5000.

Shipments of cattle out of Montana this year have been the greatest ever.

Fruit growers of Colorado met at Greeley recently and formed an Anti-pest Association.

Engineers are at work preparing for irrigation work in the Colorado river reservation in Arizona.

The Carey act is responsible for the reclamation of over a million acres of land in the state of Nevada.

The annual meeting of the state horticultural society of Utah will be held in Brigham City, February 16, 17.

The Farmers Union of Pendleton, Oregon, is perfecting details for a farmers insurance company with $250,000 capitalization.

Residents near Parker, Arizona, are working for the opening of the Colorado River Reservation.

The egg market in Seattle dropped from 40 cents to 35 cents in one day, prices being affected by frozen eggs offered.

A big tract of land on old Yaquina bay in Oregon has been purchased and will be subdivided and sold in small parcels.

So great have been the depredations of coyotes in the Inland Empire about Spokane that an organized campaign is on with bloodhounds.

Members of the Farmers Union of Walla Walla, Washington, have combined and ordered 3,000,000 grain sacks for the crop of 1911.

The Roosevelt Reservoir in Arizona is rapidly filling since the last rain. It is estimated that over 150,000 acre-feet have already been stored.

Steps are being taken to improve the Columbia river at Rickey Rapids, so as to permit transportation over them. It is claimed it will cost only about $20,000.

Northern Idaho is planning for a series of farmers institutes under the direction of Dean Carlyle of the university from January 20th to the last of February.

The reclamation service headquarters at Boise, Idaho, has been notified by Secretary Ballinger that $1,000,000 is available for reclamation work in that district.

The Salt River Valley, Arizona, and in fact practically all of Arizona, received a great flooding during the recent storm. The benefit will be incalculable.

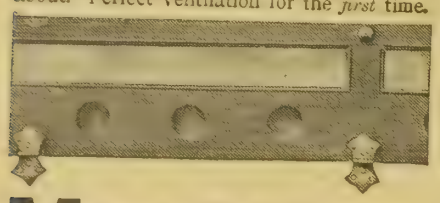
The coyotes of the Wallowa forest reserve in Oregon are infected with rabies and a fund has been provided and a force of ten men are making it their constant business to hunt them down.

A ditch digging machine on the Cudahy tract in Central Mexico just below the American line in the Imperial Valley, has a capacity of a mile of ditch a day. The ditch dug is six feet deep and twelve feet wide.

Portland claims the biggest wheat export figures for 1909 for any city in the world. The total exports for last year from that port were 5,120,826 bushels, which was about a half million bushels short of the preceding year.

More Inventions by Lee

Here's his new Incubator door all are talking about. Perfect ventilation for the *first* time.

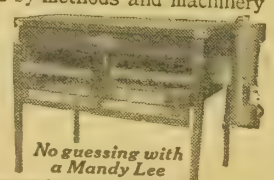


Mandy Lee Incubators

supply life-giving oxygen freely to the eggs and just as naturally draw off the poisonous gases. The most important step ever taken in incubator ventilation—neither above nor below, but *right at the eggs*—the correct principle, for the new Mandy Lee is making better hatches of *stronger* chicks than any other incubator in the world.

We Measure Everything

Heat—moisture—ventilation. You *guess* at nothing. If the eggs are good and you follow simple directions your work with a Mandy Lee is as nearly an absolute certainty as anything can be. There is no more reason why you should buy an incubator that regulates nothing but heat than for a farmer to continue to harvest his crops by methods and machinery used 100 years ago. Your success with poultry depends on your ability to select equipment that is *right*—that's what you *always* get from us.



No guessing with a Mandy Lee

Send *to-day* for new catalog. Learn of these new improvements and of our new *out-door, lamp-heated* and *regulated brooder*, just what is needed.

Practical Poultry Culture

BREEDING AND FEEDING OF DUCKS.

By Vincent G. Huntley, Petaluma.

We have no record to show that Adam and Eve kept ducks, or if they started with the birds themselves, or purchased the eggs. So we will presume that the stock would be most likely and start in the same way.

The question arises as to breed. Which is the most profitable to raise for market? There are scores of varieties and many that will pay for raising, but as in chickens, some are more suitable for table purposes and some for egg production. For the former we have to go to the following whose value may be taken in the order given, viz., the Aylesbury because of its great length and size and its quick maturing properties, together with its very fine quality of flesh. It is possible to produce an Aylesbury duckling at from eight to nine weeks old to weigh seven pounds and at the same time not be overfat. In the general way, providing the stock they are bred from are fair average birds, the young ones should weigh five and one-half to six pounds at eight weeks.

Next comes the popular Pekin which has been the favorite in the American market for some years past and is still in great demand, and is the general market duck at present, having been established for many years in this country and thus eclipsing the Aylesbury in numbers. Their flesh is very similar to the Aylesbury, but the fat is more yellow and the body shorter. The birds when running should have an upright carriage nearly perpendicular. They are very hardy and quick maturing and at eight to nine weeks old should weigh four and one-half to five and one-half pounds.

There is a class of duck commonly known as the Mammoth Pekin which is evidently a cross between the Aylesbury and Pekin, having a longer beak and a more level carriage than the true Pekin type, which should be upright with a short, well-set beak, and the color as near canary yellow as possible. At the shows across the water a pure white Pekin is not tolerated and very seldom wins a prize. The Mammoth probably is as good a bird for market purposes as any, because it is the medium between the foregoing breeds and therefore should be very hardy and easy to raise. I have produced some wonderful table birds from the first cross between Aylesbury and Pekin.

Next in order, or probably equivalent, according to some in this country, comes the Buff Orpington duck. This, of course, is a newly manufactured breed of which the late Mr. William Cook claims to be the originator. Now here I must tell you a little tale. Somewhere about 1895 M. Wm. Cook was judging a country show near my home in Wilshire, England, and consented to be my guest for a day or two to look around the ranches in the district, and also to inspect my stock of Orpingtons, ducks, etc.

I had that season an odd pen of Aylesbury and Pekin ducks which were running with some spare Rouen drakes. The eggs were hatched so as to have young stock for table purposes. Among the offspring were ducks of many colors, but the majority were either blue or buff and a very even color. These latter at once attracted Mr. Cook's attention and the price was asked, set and the deal made in no more time than it takes to write it. After he had purchased he said: "I have a great idea if we can breed these ducks true to color. I have a notion they will take well, and if so we'll have some Orpington ducks as well as chickens." I remember rightly about this time he found some more of these ducks in the north of England that had been bred for some years, probably originating from the same cross as in the drakes. You can distinctly trace the markings of the Rouen head and ring around their neck. In my first cross I had some of the best buffs I have ever seen.

The Buff Orpington ducks do not generally grow as large as the Aylesbury or Rouen. When I say Rouens I do not mean such as I have seen in California, as they are more after the type of a good-sized wild Mallard duck. My "Champion Jumbo," illustrated in the American Poultry Monthly some years ago, weighed thirteen pounds. A good Rouen should be about the same size and weight as the Aylesburys exhibited by me around California. I hope some day to show some good Rouens as soon as I can get them out here.

Returning to the Buff ducks. They should prove a grand bird from a utility point of view, although of course, if not taken in their right moult their pin feathers would show more than the white ducks when dressed, but their flavor is all that can be desired. They are easy to fatten and though not quite as large become very plump.

The Rouen can claim, although mentioned at this stage, to be the king of waterfowl when beauty and utility are combined. The beautiful green head and round claret breast divided by a three-quarter ring of even pure white, followed by a body of beautifully laced French grey shaded to perfection with the wing bars of Peacock green and white, is enough to dazzle the eyes of a prince. It is generally supposed that the Rouen has a deeper flavor than the Pekin or Aylesbury, but when dressed at the proper stage it is as white in flesh as either of the above mentioned.

For fancy eating the East Indian makes an excellent little duck, fine in flavor and texture of flesh. These are generally kept on lakes on estates in England as an ornamental fowl and are not commonly used as a commercial bird. The Cayaga is a similar species, but larger and greener in color. The Muscovy is liked by some, but as a rule has a fishy or strong flavor.

Now we come to the egg proposition. There is no doubt that the Indian Runner is the top notch as a layer, and providing you can find a market for the eggs at a reasonable price will pay as well as any. Many of these birds have a record of 220 to 250 eggs in one year. Their flesh compared to that of the Aylesbury, is like the White Leghorns compared to the Rock or any of those table breeds. You can seldom find the two things run together and the bird that lays the eggs has generally a tougher texture of flesh.

Now a word as to hatching and raising. The eggs require 28 days for

WINTERS' WHITE INDIAN RUNNERS

The World's Greatest Egg Producers—First, California State Fair, 1909. First, display pen; first, breeding pen; first, drake; first, duck and second, duck, at the Los Angeles Show, 1910. Eggs for hatching. White and Barred Rocks and White Minorcas. Eggs for sale in season. C. O. Winters, 5807 Washington Ave., Los Angeles, Cal. Phone, Sunset East 1197.

incubation and in small numbers are best hatched under hens which they will not require after they are a week old. In fact, I very often raise them without any mother at all, being careful the first few nights to see that they are fairly warm. In raising large quantities the ordinary hot water brooder is used for the start. Top heat preferred, but do not run as hot as a chicken brooder, 75 to 80 degrees I reckon is sufficient. Let them have straw or some such chaff to run on when small, substituting whole straw as they grow bigger.

Duck eggs in the incubator require more moisture than those of hens. It is a good plan to dip a flannel in water 105 degrees or more, then wring it out moderately dry. By that time it will be about the temperature of the eggs in the machine. Place this over the eggs just as they are due to pip. In addition to this you govern your moisture by the air space in the egg during the course of incubation and do not run the machine too high; 101½ to 102 just below the top of the egg is a fair temperature.

In feeding young chicks they do not need to stay so long as chickens before feeding, about the next day after hatching you can start them with a little milk and water sprinkled over with breakfast rolled oats. Be sure to have the oats pure and free from wheat, as the start makes a whole lot of difference in a duck. A good start means that they will be ready three or four days sooner than without. Follow the oats with soaked bread and milk if you have it. Feed alternately for a week with oats and soaked bread and fine chopped green stuff. By that time they will be able to take a mash composed of the following porportions:

1 part bran;
1 part shorts;
1 part finely ground corn;
1 part ground barley.
1 part meat (fresh preferred);
½ part bone necessary for frame growing;
¼ part clean sand.

Wheat and cracked corn may be fed mixed. Table scraps and green food can be fed to advantage.

Regulate your feed while growing to produce bone and frame and for the first six weeks let them have range and swimming water if you like. Then have your fattening sheds so that you can let them out to feed and have a bath. Many say do not let them have water to swim in, but I have found that a duck does better when clean, and will fatten and grow as quick if allowed to have a bath once or twice a day.

The plan used in Buckinghamshire and districts where the prime ducks are raised for the London market is something are follows: Barns, from twelve feet to twenty feet square are used to accommodate 230 to 500 ducklings. Outside of these barns are cemented pens with baths at the ends, usually water running right through them. In the early stages the ducklings are allowed to run in and out at liberty, but when they become about six weeks old they are only let out in the yards twice or three times a day according to the number of times they are fed, at which time they can eat and take their bath, then they retire to the barn on nice clean straw where they sleep and graze until the next meal time. Where a lot are kept in one barn divisions are made use of, and lots of 50 to 100 are kept in a section. Great care is taken not to disturb them during their sleeping

An extra choice assortment of toms and hens from my best matings. Large bone, long body, full-breasted, well-marked birds which are strong and vigorous, from the best strains in the East. Prices reasonable. GEO. A. SMITH, Corcoran, Cal.

hours and strangers are only allowed to peep through the keyhole, as it were. When near the finishing point an extra allowance of meat, green bone or fat is given them. Then finally they are killed, dressed, and packed for the market. But before packing they are shaped, that is to say, laid on their backs to set so as to have the best appearance when on show. Ducks are seldom scalded for plucking as when exposed to the air afterwards they turn a bad color. Contrary to the chicken a duck is easiest to dry pick when cold and after being fasted for at least two days before killing. Fasting is a most important thing before killing, as the meat not only keeps better but when kept does not get any taint from the food that may have been passing through it. To keep ducks best when killed do not draw their entrails, but fast at least 24 hours before killing, giving water the first twelve hours, then nothing. By this means there will be nothing but the plain gut inside of the bird, which will help to keep the bird sweet and moist, and there being no opening the flies have no chance to enter and leave their disease germs and eggs. When once the bird is opened the inside is the part that will taint first, so that if you want to keep your bird until it is fit for use and when rigor mortis is out of the system, adopt the above method.

ABUNDANCE OF GOOD THINGS.

Our poultry friends found abundance of good things in the last issue. Nor were they all used up in that one number. The provision had been so liberal—like a Thanksgiving feast—that some of the best is yet to come.

This week one of the holdover features by Vincent Huntley tells of ducks and their care.

Next week Mrs. Basley, for years in charge of the Poultry department, again greets her friends, who are many, in The Cultivator family. She will talk of disease prevention. It's a good article.

Other articles on turkeys, geese and then some yet to come, make The Cultivator of value to the poultryman.

By the way, had our poultry readers thought that The Cultivator's weekly visits bring as much or more poultry information into the home than the exclusive poultry monthlies? Besides it has a great fund of information along other lines.

Do not forget that a balanced ration is just as essential for poultry as it is for other live stock.

It is poor economy to keep old hens or old roosters. Hens are past their best at three years old, and when kept longer, are apt to give poor returns.

Before using a disinfecting spray in hen house or coop be sure to remove every particle of rubbish and filth; otherwise your spraying will do but little good.

Give fresh and clean water to the fowls several times a day and especially let the first drink in the morning be clean water. Water standing over night or for part of a day is liable to be full of dust, poison and parasites. These are not good for chickens.

Timely Ranch Suggestions

POPULATION AND SUBSISTENCE.

Frequent assertions that the fertility of the soils is washing into the streams and that the productivity of cultivated land is diminishing are misleading the public into the belief that the agriculture of this country is decadent and that there is life in the old formula that population must tend to increase at a greater rate than subsistence. So states the chief of the bureau of statistics of the department of agriculture in his annual report for 1910 at the beginning of a discussion of the ability of agriculture to maintain population in this country.

Historical Phases.

The situation can not be understood, he says, until it is examined historical. This is a country in which millions upon millions of acres of fresh land have been coming into production faster than the domestic consumption has required, and at times beyond the takings of importing foreign countries. As eminent a man as Gen. Francis A. Walker expressed the belief that under such circumstances farmers on the fresher soil were economically justified in robbing the land.

All of the historical phases of agriculture now exist in this country. First, the "soil robber;" next the diminishing production per acre on "inexhaustible land," which surprises the farmer; next the agricultural scientist, who points the way to a better agriculture and larger production per acre, with poor responses from the farmers.

In the course of time, especially when the next and perhaps the third generation takes the farm, important advances are made, at first irregularly and mostly on farms of the leading class and subsequently with increasing diffusion and accelerated speed.

For many years there have been fresh lands with rather high but stationary production, older lands with declining production, old lands beginning to improve, and some lands well advanced in improvement. As the proportions of these classes of lands have varied in relations to the entire cultivated area of each crop the national average production per acre has varied.

In the meantime the competition of new land consuming some of its capital in the production of crops has retarded, if not prevented, the improvement of old land needing conservation and a gain in fertility. The improvement of the older land is not an academic question of conservation of national resources, but it is to be worked out in the endeavors of farmers to get a living, and a better one, an end that can not be attained by a sudden high production per acre large enough in the agregate to be overproduction, with unprofitable if not losing prices for the farmer.

Recent Increased Production per Acre.

A marked change in the production per acre of all crops appeared in the decade 1896-1905 in comparison with the mean of the preceding ten years. The production per acre of corn increased 7.7 per cent; of wheat, 6.3 per cent; of oats, 15.6 per cent; of barley, 11.1 per cent; of rye, 21.3 per cent; of buckwheat, 23.1 per cent; of hay, 22 per cent; of potatoes, 15.3 per cent; of cotton, 3.8 per cent; and of tobacco, 5.2 per cent.

The weather and other crop conditions of the four years 1906-1909 were not as favorable for crop production as they were in the preceding ten years, so that the production of oats per acre declined, that of hay remained stationary, and that of cotton and barley barely increased. In the case of other crops the mean production per acre continued to show large increases, the mean of these four years over that of the preceding ten years being an increase of 7.1 per cent for corn, 9.6 per cent for wheat, 6.5 per cent for rye, 6.6 per cent for buckwheat, 15.5 per cent for potatoes, and 9.7 per cent for tobacco.

Actual Population Increase.

Corn production per acre increased from 1886-1895 to 1896-1905 at a rate which quite or very nearly equaled the actual increase of population in ten states. The list for wheat contains 22 states distributed in all parts of the United States. In the list for oats are 16 states; for barley, 15 states; for rye, 21 states, for buckwheat, 18 states; for cotton, only 1 state, Oklahoma, containing new land; for tobacco, only Wisconsin; for potatoes, 15 states, all in the potato belt; and for hay, 25 states. The average for the four years following 1905 is not based on a number of years large enough for comparison.

Decreasing Birth Rate.

There is a prevalent misunderstanding with regard to the nature of the increase of population in this country. It seems to be assumed that the net immigration is to continue indefinitely at the rate of one-half to three-fourths of a million people annually. How quickly immigration can be reduced was shown by the industrial depression of 1908. No one who would take a far sight into the future would reckon upon an indefinite continuance of a considerable immigration.

Normal Population Increase.

A prevalent oversight in a consideration of this subject concerns the birth rate. The census of 1900 points to the conclusion that the birth rate of this country, after eliminating the influence of the foreign born, is about 1¼ per cent a year ,or 12½ per cent for a decade.

A comparison of production per acre with the normal increase of population, that is to say, with the increase unaffected by immigration and the high birth rate of the immigrants, is the form of the problem as it will present itself more and more closely as the years elapse.

From 1886-1895 to 1896-1905 the mean production per acre of wheat increased in a greater degree than the normal increase of population in 28 states. Two other states are very near inclusion.

In the case of corn production, increased production per acre has exceeded the normal increase of population in 14 states, and very nearly the required increased production was made by 5 other states.

A long list of states gained in production of oats per acre in a greater degree than the normal increase in population. They are found in New England and along the Atlantic coast to Georgia; in important states of the Ohio valley, north and south; in the

"Let There be Light."

—PAT HENRY, before the battle of Bull Run.

We are not sure that our old friend Pat has been correctly quoted, neither do we know that he was anywhere near Bull Run during that memorial event, but we do know that every Rancher, Miner, Dairyman, Stableman and Teamster on the Pacific Coast should be in possession of at least one of our Vehicle Headlights, here illustrated.

There are times when a good, strong light is almost indispensable. It is needed around the barn, the thrasher, the harvester, on the gang-plow, on your wagon or buggy when driving over rough roads, the ranch, the mine or the dairy.

A Boesch Vehicle Headlight is worth a dozen ordinary hand lanterns. They are well made, strong and durable, each one is fitted with a highly polished silver plated parabolic reflector which concentrates the rays of light with remarkable brilliancy. The body is finished in a rich glossy black with polished brass trimmings, and for appearance it is first in order of handsome lamps. It embodies all our latest improvements, and for efficiency as a light producer it is without equal. This is the Headlight that caused the passing of the State Law prohibiting the hunting of wild ducks by artificial light. It is being used by nearly every Fire Department on the Coast and in many of the large Eastern cities.

Do not be led into buying a cheap, inferior lamp. It won't pay. This one is the result of forty-two years' experience in the business. It is home industry, and we guarantee satisfaction. It is made in 6, 8 and 12-inch sizes, measurements across the face.

We also manufacture many other styles of Headlights, Lamps, Lanterns, etc., too numerous to mention.

Write for Catalogue and full particulars of lamps or lanterns that you require.

THIS LEVEL IS NO MAKESHIFT. The outfit includes Level, Telescope with magnifying glasses enabling you to read the target a quarter of a mile away; Tripod, Graduated Rod, Target, and Bostrom's 70 page book—"Soil Salvation"—giving the cream of 25 years practical experience in Irrigating, Draining and Terracing, with full instructions how to use the Level. Simplicity, Accuracy, Durability Guaranteed. Used and endorsed in every State in the Union, also Canada and Mexico. *Price $15.00.*

Shipping Weight 15 Lbs.

If not on sale by your local merchant, he will order for you; or you can write either of the following jobbers direct, who will see that you are supplied. Pacific Hardware & Steel Co., San Francisco or Los Angeles; The Thomson-Diggs Co., Sacramento; Hazard, Gould & Co., San Diego.

mountain states, and in Washington.

With regard to barley, 21 states are found in a similar list; for rye the list of states numbers 30, buckwheat 19, and 3 other states are near the requirement for admission to the list. Wisconsin is the only state that has produced tobacco with an increase during the time under consideration which is larger than the normal increase of population, but the increase of tobacco production per acre is very nearly equal to this population increase in the case of 5 other states. Increase of cotton production per acre above the normal increase of population is found in 3 states, with a supplementary list of 4 states almost able to enter the list.

The list of states that produced potatoes with an increase per acre above the normal increase of population contains many of the states in the potato belt, and the number is 24, with 4 states almost eligible for admission.

The largest list of states in the consideration of the various crops in which production per acre during the period under consideration exceeded normal increase of population is found in the case of hay; 35 states are in this list with 5 more states having increases nearly sufficient for their entry, so that the hay crop of nearly the entire United States has increased in production per acre faster than the normal rate of increase of the population.

The ability of the soil and the agricultural arts and sciences, concludes the chief of the bureau of statistics, to produce crops at a rate of increase greater than either the normal rate of increase of population, or the normal as temporarily influenced by immigration, has been demonstrated times innumerable by the department of agriculture, by the experiment stations, and by the intelligent farmers all over the country.

Beaumont boosters are planning for a broom factory.

POCKET GOPHERS.

Poisoning with strychnine is the most effective means known for killing pocket gophers, and, as it involves the least expenditure of money and labor, the Biological Survey recommends it for general use. As a rodent poison to be used by farmers, strychnine has several advantages. Its action is sure, its deadly character is known to most persons, and its bitter taste is an additional safeguard against mistaking it for a harmless drug. Strychnia sulphate is the most convenient form of the poison, since it is freely soluble in hot water and in the natural juices of vegetables used as bait. To disguise its bitterness so that rodents may not be deterred from eating the baits, sugar is often employed, or the strychnine may be mixed with its own bulk of commercial saccharine. A sugar syrup poisoned with strychnine may be used with excellent results. It is prepared as follows:

Dissolve an ounce of strychnia sulphate in a pint of boiling water. Add a pint of thick sugar syrup, and stir thoroughly. The syrup is usually scented by adding a few drops of oil of anise, but this is not essential. If preserved in a closed vessel, the syrup will keep indefinitely.

The above quantity is sufficient to poison a half bushel of shelled corn or other grain (corn recommended). The grain is steeped in hot water and allowed to soak over night. It is then drained and soaked for several hours in the poisoned syrup. Before using, corn meal may be added to take up the excess of moisture.

Dry crystals of strychnine also may be used. They are introduced, by means of a knife, into small pieces of potato, carrot, or sweet potato, or into entire raisins or dried prunes. A single large crystal (or several small ones) is enough for each bait. Raisins are especially recommended because they are easily handled and contain enough sugar to disguise the bitterness of the poison.

Pocket gophers in ditch banks may be poisoned in the following manner: Select the freshest hill or mound and with a narrow garden trowel follow the soft earth of the tunnel until the main runway is reached. By noting the direction from which the earth was pushed out and locating the closed entrance, the burrow may be readily followed and the main runway quickly found. The poisoned raisin, corn, or small potato should be placed well back in the main runway and the opening closed. It is usual for one gopher only to occupy the burrows connected with a group of hills, and when the burrow remains open it indicates that the animal has been killed.

Trapping is a successful method when followed intelligently and persistently. It is especially adapted to small fields, orchards, gardens, and irrigation embankments, where only a few gophers are present; but in the case of large areas that are badly infested, the method involves too much labor.

For trapping gophers an ordinary No. 0 steel trap may be employed with success, but there are on the market several special gopher traps which are better adapted for general use.

In using the ordinary steel trap, the first step is to make an opening into the main gopher tunnel. The trap should then be sunk so that the jaws are level with the bottom of the runway and lightly covered with green clover, alfalfa grass, or even loose soil, care being taken that these do not clog under the pan, or trigger. No bait is required. The hole should be just large enough to receive the trap and should be covered so as almost to exclude the light. Scalding the trap frequently to remove the animal odor is important.

Some of the special gopher traps possess the advantages of ease and simplicity of operation, and kill the animals instantly. These special traps should be set in the laterals leading into the main tunnel of the gopher, or at the entrance of open burrows where fresh earth is being thrown out. The trapper should choose the freshest of a series of mounds and dig along the lateral until it is found clear of soil.

Carbon Bisulphid.

Carbon bisulphide has been employed for killing pocket gophers, and under favorable conditions its use is recommended. If the burrows are extensive or the soil dry, the gases

Avery Double Cylinder Engine Threshing Outfit

An Avery Threshing Outfit is a Thresherman's *"Money Maker"* and a Farmer's *"Grain Saver"*

Three Reasons Why It's the Machine for a Thresherman

It's a Long Laster

An Avery Outfit isn't the kind that's worn out by the time you get it paid for. Each year more threshermen are learning that the Avery Company builds strong machines and not the cheaply constructed kind.

The Big Run Machines

Ask any Avery Thresherman about the way an Avery Outfit handles the Grain. An Avery Engine is a strong puller, and there are no flimsy contraptions in the Separator to slow things down. You can do good work and a *big lot* of it with an Avery.

Suits Your Customers

That's one of the most important things. Does a good job in saving and cleaning and doesn't keep breaking down all the time, and piling up the expense. With an Avery you can *get there* and *get away*, and you leave a pleased customer behind.

Three Reasons Why It's the Machine for a Grain Growing Farmer

It Saves Your Grain

To show just what an Avery Separator will do in saving the Grain, we have made a number of canvas tests. These tests show an average saving of 99.92 per cent. *Almost Perfect.* The best proven record of grain saving that has ever been made.

Does Fine Cleaning

An elevator owner wrote us, "The Avery Machine sends me the cleanest grain that I ever received." Time and time again threshermen have told us that the grain threshed with an Avery brings a higher market price because it's *cleaner.*

Does Quick Work and Gets Away

"No tinkering around" is what one farmer wrote about the work of an Avery "Yellow Fellow" and that tells the whole story. Does clean work and quick work and isn't always breaking down on your job.

FURTHERMORE—Avery Machinery is Also Backed Up By The Strongest Warranties Ever Given by Any Manufacturer

If you are a thresherman you should find out all about the money making Avery Outfit. Single or Double Cylinder Engine. Any size Outfit. *If you are a grain growing farmer* you should find out all about the fine work in cleaning and saving your grain that an Avery "Yellow Fellow" will do for you. Our catalog tells all about their construction, and shows them in colors just as they look. **Write for our complete free Color Illustrated Catalog. Address**

Avery Company, 921 Iowa St., Peoria, Ill.

A 1263 PHONES MAIN 8794

are dissipated so rapidly that a large quantity of the liquid is required to kill the animals and the method becomes too expensive. If, however, the burrows are simple and the soil moist, bisulphid may be used successfully. For pocket gophers an ounce of the liquid for each burrow is sufficient. The carbon bisulphid is poured over a bunch of cotton, rags, or other waste material and this quickly pushed into the burrow, which should be closed at once.

Co-operation.

Any farmer may readily rid his premises of gophers by the use of poison or traps. Unless, however, the entire community unites in active and intelligent co-operation in the destruction of the animals, the cleared area will be sooner or later invaded from neighboring premises, and the work of destruction must be repeated. Co-operation only will effect a radical cure. When co-operative efforts for the extermination of gophers over a considerable area are attempted, careful attention must be given to waste lands along fences, streams, public highways, and railroads. Such places are favorite haunts of the animals, because in them are found loose, sandy soil, moisture, and succulent roots for food. It is from such resorts that adjoining premises are often restocked with pocket gophers.—Circular 52 Bureau of Biological Survey.

SIMPLICITY.

Simplicity is less dependent upon external things than we imagine. It can live in broadcloth or homespun; it can eat white bread or black. It is not outward, but inward. A certain openness of mind to learn the daily lessons of life; a certain willingness of heart to give and to receive that extra service, that gift beyond the strict measure of debt which makes friendship possible; a certain clearness of spirit to perceive the best in things and cleave to it without mistrust; a peaceable sureness of affection and taste; a gentle straightforwardness of action; a kind sincerity of speech,—these are the marks of the simple life, which is within. I have seen it in a hut. I have seen it in a palace. And wherever it is found it is the best prize of the school of life, the badge of a scholar well-beloved of the Master.—Henry Van Dyke.

COST OF FLIES.

Recently a little suburb of Salt Lake City experienced a serious outbreak of typhoid fever, the cause for which was traced to the milk supply; but no case of typhoid was found at the dairy. A correspondent at Salt Lake City writes that the season before a man at the dairy had typhoid, and his excreta had been dumped in an unused outhouse back of the barn. When the hot weather came, the flies, bred in that outhouse, carried the germs from the excreta a year old into the barn, and infected the milk, and through the milk twenty-six families had to bear the awful scourge of the dread typhoid, all because the contents of the one old outhouse had not been covered with netting.

HITS CARELESS FARMERS.

Secretary Wilson declares that many farmers in the West are using too much water, being inclined to rely too much on water and not enough on cultivation. The difference between the good farmer and the poor is just as conspicuous in these regions as it is anywhere else.

THE VALUE OF A FRIEND.

So long as we love, we serve; so long as we are loved by others, I would almost say that we are indispensable; and no man is useless while he has a friend.—Robert Louis Stevenson.

NOTHING.

Madge—Then you really believe in nothing?"

Softhead—"I believe in anything I can understand."

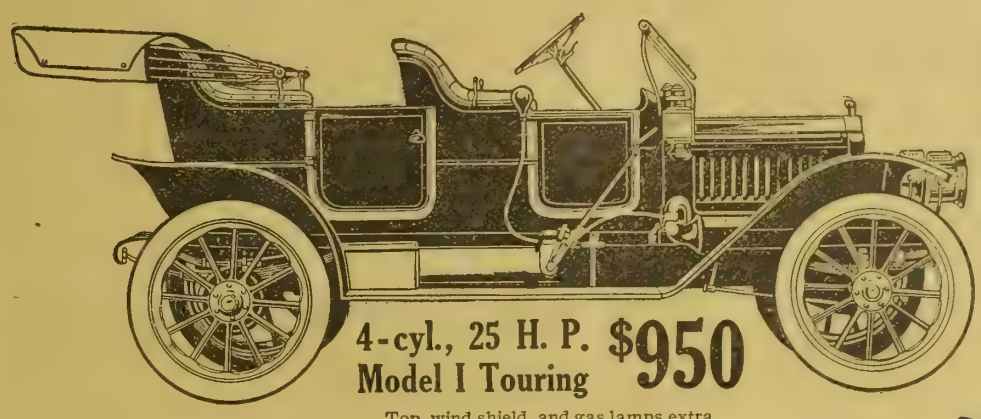
Madge—"What a frightful skeptic you must be!"—Brooklyn Life.

She—How do you make a Maltese cross?

He—By pulling its tail.—Judge.

Life appears to me too short to be spent in nursing animosity or registering wrongs.—C. Bronte.

I Built this Maxwell Especially for Farmers



Here's the Car you've waited for at a price you can afford.

4-cyl., 25 H. P. Model I Touring $950

Top, wind shield, and gas lamps extra

LAST year we sold 4,227 Maxwells to farmers. Think of it! This so stirred my enthusiasm that I resolved to design a car for *farmers especially*. One that would stand the hardships and terrific punishment of rough farm work, and yet stand up 365 days in the year.

Typical Farmers' Car

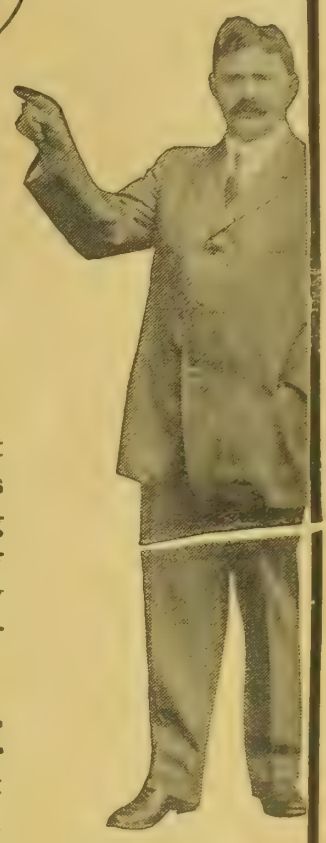
Operating a farm myself, I knew what was wanted. I knew the car must be substantially built of first-class materials. That it must be a big car, adaptable both for business and pleasure. That it must possess ample power. That it must possess simplicity and accessibility of parts. Above all, it must be a car of stylish lines and dignified appearance. Such a car I built. When I figured up manufacturing cost, to my great surprise I found that owing to the tremendous Maxwell facilities and output I could sell this car at the exceedingly low price of $950. Such car value was never before known.

Not a City Car

It doesn't pay to sell a car built for city use—fine boulevards and macadam roads—telling the farmer it is the ideal car for the country. This policy may sell the first car, but never the second.

Ask any Maxwell Owner

Ask any Maxwell owner what it has cost him, saved him and produced for him. How it has saved his horses. How it has kept young men with their father on the farm because of its money-making possibilities. Ask him how it compares in expense with horse-drawn vehicles—if it is a paying investment.



These Books Free

Let me send you our latest catalogue, new "Farmers' Economy Booklet" and other timely literature. I will gladly send you these books free—and no obligation. Write me today. A postal will do. Just say, "*Mail Books.*"

Be My Guest Call on the nearest Maxwell dealer. I have arranged for him to invite you and your family to ride in any Maxwell you select—at my expense. Be sure and try the Model AB—the new 16 H. P. Farmers' Runabout at $600. Satisfy yourself that all Maxwells work alike—that they are equally reliable. The car will save you money, just as it has 40,726 other Maxwell owners.

J. D. Maxwell *President and General Manager*

Farming Tools

are *money savers*. High quality considered, the lowest price tools made. Last twice the "life" of common tools. Cost nothing for repairs and do better work after years of use than many other tools do when shining new from the Hardware Store.

Every hand farming tool on which you find the Keen Kutter trade mark is covered by a broad gauge guarantee. If a Keen Kutter fork, hoe, rake, scythe, snath, shovel, axe or hay knife, shows an imperfection of any kind, or fails to do the work for which it was intended, easily and fast, you get your money back. The same guarantee covers Keen Kutter shop tools, razors, shears, pocket-knives and table cutlery.

"The Recollection of Quality Remains Long After the Price is Forgotten."

Trade Mark Registered. —E. C. SIMMONS.

If not at your dealer's, write us.

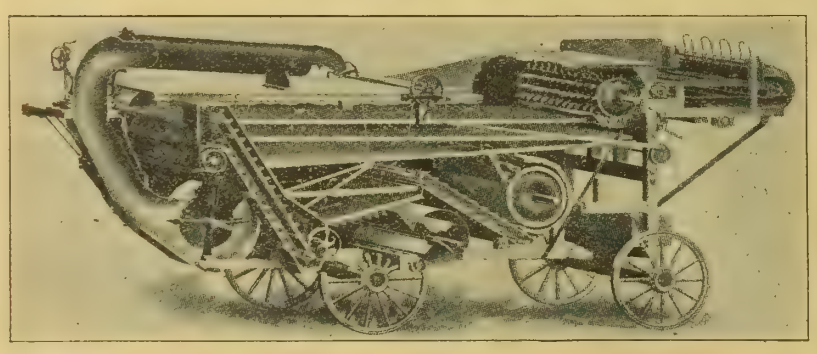
Simmons Hardware Company, Inc.,
St. Louis and New York, U. S. A.

Compare Them

In order to be convinced that the **BIRDSELL** principle of hulling (rubbing it out) is correct, you will only have to compare a head of Wheat with Alfalfa.

You can readily see that the leaves, the seed, the seed receptacles, in fact they differ so widely that a blow which will thresh out grain will not be sufficient in threshing alfalfa, because it must be **rubbed out** and the **BIRDSELL** is the machine to do it.

Compare This Machine



with the ordinary grain separator and you will agree with us that the **BIRDSELL** is the only machine made that will save all the seed and put it in the sack ready for market. We can sell you a combination machine if you want one. Get busy now, write or come in and see us, we will put our time against yours.

WONDERFUL NEW PEACH

Wonderful new peach, "Shamrock," that comes in just after Salway, which keeps until February. It is a large yellow peach, highly colored, like Orange Kling, has a rich flavor, bears very heavily on all parts of the tree, and sells during winter at 10c and 15c a pound. Three growers near Los Angeles have had control of this peach the past four years and would not sell any trees, but they have netted $400 to $500 an acre each year. My trees are the first ever offered for sale. Price $25.00 a hundred, or 50c each. Also have Foster, Crawford, Susquehanna and Salway at $10 a hundred. All trees two years old.

O. C. LANE, R. F. D. Box 70, Burbank, California.

Questions and Answers

THE EDITOR AND STAFF

Questions to be answered in this department should be received at this office one week before reply is expected. Write plainly on one side of the paper and sign full name and address. Unsigned communications receive no attention.

Pruning Apples and Pears.

Please give advice regarding pruning apples and pears. Subscriber, Modesto.

See Mr. Mills' article on deciduous page of next week's Cultivator.

Trap Nests.

Where can I buy trap nests, or are they simple enough so that I can make them?—Subscriber, Tustin.

An early Cultivator will have descriptions of trap nests and illustrations, so that it will be fairly easy for the subscriber to make them. This will be a reprint of a former article which proved helpful.

Miner's Inch.

How many gallons in a miner's inch under six-inch pressure; also how many gallons are thrown by a pump which is supplying twelve inches of water?—Subscriber, Lincoln.

An inch of water under six-inch pressure is 11 gallons per minute; under four-inch, 9 gallons per minute. At 11 gallons per minute your pump would throw 660 gallons per hour or 15,840 gallons in 24 hours.

Ferrets.

Where can ferrets be secured? I wish to use them in catching rats in dwelling house. Can you give me the price?—J. F. M.

We do not know of any breeder of ferrets in California. We see no reason why they should not be as satisfactory here as they are in the East. The ferret breeding center of this country is New London, Ohio. If J. F. M. will write us we will send him address of parties from whom he can secure them.

Scabby Potatoes.

Please give formula for treating seed potatoes to prevent scab.—Subscriber, Arroyo Grande.

If our subscriber will turn to the issue of the Cultivator of November 3, in which is a complete list of formulas for treatment of diseases and pests, he will find in Numbers 6 and 7 that formalin one ounce and water two gallons, or corrosive sublimate two ounces and water fifteen gallons will make a dip for seed that will prevent potato scab.

Peaches Out of Condition.

I send peach twigs. The trees from which they are taken are affected with gum trouble. First noticed it last fall while the leaves were still green. Every tree in the orchard is affected, also apricot trees.—Subscriber, Ontario.

This was referred to Mr. C. O. Smith, assistant plant pathologist at the Southern California Laboratory, and he answers: "From my observation I do not think the trouble is due to peach blight. It may be due to some bad soil conditions. I would advise pruning these trees back well and giving them especially good care."

Slow Moulting.

Is there any reason why my hens should be very slow in moulting? They have been moulting since the first of October and go shivering around for lack of feathers. The old feathers stick very tightly and new ones are lacking.—Subscriber, Campell.

A food very rich in protein, beef scraps or other meat ration, will perhaps help in the formation of feathers. Feed plentifully. Some poultrymen force the moult early in the season, claiming they can complete it more quickly by a starvation ration for a couple of weeks as soon as the moult begins to show, then at the end of that period rich and abundant ration is supplied to make feathers.

Seville Oranges.

Are the oranges known to the English trade as Seville or bitter oranges from which Scotch marmalade is made grown in this state? Where can they be procured?—P. B., Santa Rosa.

The Seville orange, usually called in this state "sour stock," is the stock on which many of the sweet oranges and lemons are budded. The seed may be purchased of seedmen, or citrus nurserymen advertising in The Cultivator can supply you with the stock. Some of the streets of the city of Sacramento are lined with this variety of fruit.

Scaly Leg.

Is there a way of removing scales from hens' legs, also of preventing them from forming again?—Subscriber, Campbell.

Application of kerosene to the shanks will accomplish this, though it is a rather severe remedy. Some prefer washing in warm soapsuds until scales are softened, then remove as many as possible, after which the shanks are covered with ointment of lard or vaseline in which a large quantity of sulphur has been worked. This treatment followed persistently twice a week will in a short time effect a cure.

Black Leghorns.

Please describe the Black Leghorn. Is it a good laying breed, and where can the eggs be procured?—Subscriber, Olive.

Black Leghorns have the same characteristics as the other Leghorn breeds, excepting as to color of shanks and plumage. They must have the true Leghorn shape. One great difficulty in breeding this variety is the tendency of the shanks to breed too dark. The usual Leghorn requirement prevails as to yellow shanks, though the Blacks will run darker than the others. The Cultivator knows of no California breeders, but perhaps they will make their announcements later.

Gophers.

What is the best way to get rid of gophers? Is the smoke gun practical?—Subscriber, Napa.

Trapping is the surest way but in large fields it is expensive. In such case, a liberal use of poisoned baits in potatoes, raisins, carrots or other food which the pests like, will be found satisfactory. Insert a small portion of poisoned bait, close the hole and go to the next, and so on. Smoking appliances have been used extensively, and successfully when the ground is wet, with squirrels. With gophers the success has not been so complete, though some people use them and consider them most satisfactory.

Ginseng.

Please give information regarding care of ginseng, how to start, whether to use plants, roots or seeds, and the kind of soil required.—Subscriber, Santa Barbara.

The culture of this peculiar plant has had its ups and downs, the down, we believe, usually following every

boom it has had. We would advise the subscriber to use care in planting, and know as to the market before making extensive plantings. If the promises made by enthusiasts were all made good, it would prove extremely profitable. A crop worth several thousands of dollars may be grown on one acre, but the culture is expensive.

The ginseng may be propagated from seed produced in the small berries. We believe seedmen can supply you with the seed, and those who have made a business of it, some of whom have advertised in the Cultivator, have the plants, twelve to eighteen months old, for sale. If you secure your seed and do not plant at once, keep in moist sand. They are often stored in a cool cellar for a period of twelve months, the sand being kept continually moist. After this period the seed begins to crack, when it is ready for planting in the soil. Some growers prefer to plant directly in the soil, keeping it well irrigated. The seed bed should not be over four feet wide, so as to permit of weeding and working from either side. There are 7,000 seeds or more to the pound. The fall months are the best for seed planting, also for resetting. The best results have been secured by giving partial shade under lath house—this for permanent bed. The care given the best of gardens is about what is required for culture of ginseng until maturity of roots.

In small quantities the roots may be dried about the stove or in the sun in dry sections, but if large quantities are produced, evaporators are necessary.

Removing Trees.

I have a fig tree and an orange tree four or five years old and wish to remove them. Can I do it successfully, and how and when?—Subscriber.

It is possible to remove both of these trees and successfully, though it will be expensive. The fig tree which will stand much abuse, can be dug and reset, shaking off the dirt and handling much as you would the ordinary nursery tree. The top should be greatly reduced after setting. It should be removed at once. As soon as it is in its new location thoroughly settle the dirt about it with water.

The orange tree should not be moved for a couple of months yet, say in the middle of March, and to be sure of success you should take up as large a ball of earth as possible around the roots. If the tree is large and thrifty it may be necessary to use a derrick in hoisting, first having constructed a box about the ball of earth to hold it together while moving. This method is expensive and unless the tree is very valuable or it is desired to give the grounds an appearance of having been planted some time, it probably would not pay.

Avocado in Sacramento Valley.

Will the avocado grow here? Orange trees grow very well, but the fruit is not as sweet as we would wish. Where may seeds be procured?—Subscriber, Napa.

We question as to the avocado doing its best in that section, though new varieties are being introduced, some of which are claimed to grow in high altitudes of Mexico where the temperature is sometimes very low. So far the successful plantings are restricted to Southern California near the coast where the temperature does not go low. Within a very few years growers will have sufficient experience to give more definite information. The seed may be had by buying fruit which is in the markets in San Francisco or Los Angeles. Probably the seedmen advertising in The Cultivator can also supply you. You must bear in mind that to get the best variety, it is necessary to bud, as, like the orange, the avocado seedling does not come true to the parent stock though a good variety may possibly be secured.

Grafting Walnuts.

I have ten acres of walnuts that have been set out for two years. They are Placentia Perfection, and are seedlings. I have been told that it is a mistake to plant seedlings. If this is the case, can they be grafted successfully? Have been told that trees of different varieties should be planted through grove for purpose of pollinating. Is this necessary?—Subscriber, Hemet.

So long as the trees have been planted and have had two summers' growth, it might be wisest to let them grow and see how they will bear. We would not, however, plant seedlings in the future. The majority of these trees will probably be of an indifferent kind, and may be grafted over and very successfully. Old walnut orchards have been made over in many sections, and the third year from grafting have produced far more than before the cutting back.

The walnut has staminate and pistillate blossoms separate. Some varieties have the fault of forming the staminate flowers first, and even so far in advance of the pistillate that the pollen loses its vitality. As a rule, however, the two flowers come near enough together so that self-fertilizing is accomplished.

Veterinary

Answers in this column by Dr. Fred G. Matthews, are without charge. For immediate mail answer remit $1.00. In writing questions give full symptoms or particulars of injury of animal.

Lameness.

A mare, four years old, has been lame in the right hind leg for the past two weeks. The pain has not been located, but seems to be in the hip. If a strain why lame so long? How can I hasten recovery?—Subscriber, Lindsay.

Examine the limb again beginning with the bottom of the foot and proceed upward to the body carefully and systematically. Remove the shoe; pare the sole and frog just sufficient to expose every part to the view, and search for puncture wounds by nails or other sharp objects. Note if the frog is separate from the flesh at the heel. Search the foot for deep and obscure injuries by pinching the sole and the wall with the horseshoer's large nippers. Above the foot view every part from all directions, looking for enlargements. Apply gentle but firm pressure, with the thumbs, upon every part of the limb, hoof-head, joints, leaders, etc. Treatment is out of the question without first locating the trouble.—F. G. M.

Abnormal Appetite.

A horse, about 4 years old, has been gnawing at the wooden parts of the crib since one week ago. His ration has not been changed. Is this a habit or do his teeth need attention? —Subscriber, Arroyo Grande.

"Cribbing" or "crib-biting" is a vice —an acquired habit of some horses— but such subjects rest one or two teeth upon a firm object and go through a motion, with the head and neck, peculiar to the habit of the horse in question. While wooden objects are usually selected no effort is made to bite off and chew particles of the wood. The teeth used are perceptibly worn by constant use. This habit is incurable.

Actually gnawing wood is not a habit, but implies derangement of the digestion or assimilation. Improper mastication may be responsible, hence putting the teeth in order may aid in correcting the trouble. Sometimes worms are held to be the cause. Give the horse, twice daily, in the feed, one tablespoonful of a powder made by mixing dried sulphate of iron 2 ounces, gentian 2 ounces, nux vomica 2 ounces, and fenugreek 10 ounces.—F. G. M.

MEXICAN LAND

States of Sonora and Sinaloa

Tracts of all sizes, at low prices.

We have several tracts of from 1000 acres up, at first cost. These would make ideal small colonies, for parties who contemplate co-operating in purchasing land in Mexico. They are fine soil, good water conditions, and close to the railroad. We can save you subdividers' costs and profits if you and your friends can handle one of these tracts. They are suitable for anything from general farming to fine fruit and vegetable raising.

Our Santa Teresa de La Concordia subdivision, near Hermosillo, the capital city of Sonora, is delta soil, and is watered by the flood water irrigation system, corn, bean, garbanzo, and cotton land, $5.00 and $10.00 per acre, easy terms, 160-acre tracts. Fine river bottom silt soil, in the State of Sinaloa, with gravity or shallow well water for irrigation. Prices in small tracts, $12.00 up an acre, according to location and improvements.

Arrange to join one of our excursions which we are sending down at frequent intervals. Write us for free illustrated booklets and bulletin of prices.

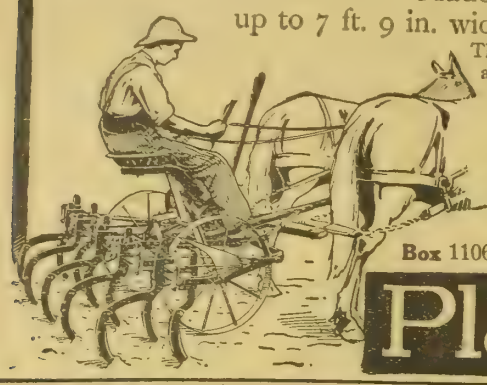
Orchardists' Time and Labor-saver

The Planet Jr No 41 Orchard and Universal Cultivator is the greatest implement ever invented for orchard, vineyard and hopyard. It does exactly what orchardists want it to do. Saves time, labor and money. The frame is heavy and substantial, high-carbon steel, and carries cultivator teeth, sweeps, hoes, furrowers, also disc-harrow attachment. Made in three sizes, cutting up to 7 ft. 9 in. wide at one passage.



Thousands of Planet Jr Cultivators are saving time and lightening labor in California and other fruit-growing districts.

We carry stock in San Francisco. Agencies in all principal Pacific Coast cities. Write for name of nearest agent; also for 1911 illustrated Planet Jr catalogue of 55 kinds for every farm and garden need. Free and postpaid.

Our 1911 Horticultural Calendar now ready, price 15 cents. Catalogue Free. Thirty-four years' experience in California.

LEONARD COATES NURSERY CO. Inc.
Morganhill, California.

Irrigation and Forestry

WINTER IRRIGATION OF ORCHARDS.

When water is used outside of the regular irrigation period or, what is in many cases equivalent, outside of the growing season, it is termed winter irrigation. Over a large part of the arid season the growing season is limited by low temperature to 150 days, or less, and when the flow of streams is utilized only during this period much valuable water runs to waste.

It was for the purpose of utilizing some of this waste that the orchardists of the Pacific Coast states and Arizona began the practice of winter irrigation. The precipitation usually occurs in winter in the form of rain, and large quantities of creek water are then available. This water is spread over the orchards in January, February and March, when deciduous trees are dormant. The most favorable conditions for this practice are a mild winter climate; a deep, retentive soil which will hold the greater part of the water applied; deep-rooted trees; and a soil moist from frequent rains.

The creek water which was applied to some of the prune orchards of the Santa Clara Valley, California, during the winter of 1904 was measured by the agents of this office with the following results: From February 27 to April 23, 1241 acres were irrigated under the Statler ditch to an average depth of 1.58 feet. From February 12 to April 23, 2021 acres were irrigated under the Sorosis and Calkins ditches to an average depth of 1.75 feet. In the majority of cases the orchards which are irrigated in winter in this valley receive no additional supply of moisture other than about 16 inches of rain water.

In the colder parts of the arid region winter irrigation is likewise being practiced with satisfactory results. The purpose is not only to store water in the soil but to prevent the winter-killing of trees. Experience has shown that it is not best to apply much water to orchards during the latter part of the growing season, since it tends to produce immature growth which is easily damaged by frost. In many of the orchards of Montana no water is applied in summer irrigation after August 20. Owing, however, to the prevalence of warm chinook winds, which not only melt the snow in a night, but rob the exposed soil of much of its moisture, one or two irrigations are frequently necessary in midwinter.—Irrigation Age.

DANGER TO ALL INTERESTS WHEN FARMERS ARE POOR.

The American farmer never has received fair compensation for raising grain or producing milk, and it is only in the last five years that he has been decently paid for his meat production. Trained business men would not give their time and investment on any such terms as the farmer does. If middlemen—buyers, packers, merchants or carriers—are responsible for price inflation, they are the ones who should be brought to account.

In this new campaign for lower prices let us make sure that we are aiming at those who are to blame for the extortionate rates which have prevailed for the last few years. A cheapening of farm products will not help business conditions. It is quite possible that cheaper food will lessen the burden of city life for the poor, but not if it be at the expense of wages and business activity.

The low price of corn today is something of a blow to farmers, who are not purchasing goods freely or circulating money with as great liberality as they would if they were getting higher rates for their produce. When the producers begin to hold up their food supplies on account of depressed markets, business becomes slack in the country, money circulates slowly, storekeepers are unable to sell goods or pay bills, and bankers report bad times. This at once affects city wholesalers and manufacturers, who employ less help and cut wages. Times soon become bad all over under such conditions.

This is not a theory, but a fact which has been painfully demonstrated in the last few weeks of money stringency. Fortunately for producers, the low prices for country supplies have prevailed only a short time, and the purchasing power of farming commodities is not yet greatly crippled.—Irrigation Age.

LAND SHARKS.

The Cultivator recently received a letter from an eastern man asking as to the value of lands in a worthless portion of Mojave desert in which the methods of a so-called real estate agent, in reality a land shark, were given. Not only had worthless land been sold but a further hold-up had been worked in the "contracting" to grade up and seed to alfalfa for a further consideration. The desire of many in the East to secure some property in California which may later be sufficient to support a family, makes easy the grafting game which the conscienceless rascals are working. It is a disgrace to the state and should be stopped. It can be and should be by some of the promotion bodies which are urging settlers to come here.

Speaking of this evil a writer in the National Irrigation Journal says:

"'That man will make a failure,' said the successful farmer, speaking of a tenderfoot, who had taken up a homestead on the mountain side, far away from civilization. 'He cannot get enough water. Frost hangs on too long in the spring and comes too early in the fall. There are no roads fit to haul over. His place is on the route taken by sheepmen going to summer camps on the forest reserve. The sheep will destroy everything. And, it is nonsense to go out of human trails to build a home.'

"The new man had recently arrived from the East. He thought, as do many others, that the government owed him a farm, and proceeded to lay claim to a portion of the public domain. But failure marked that attempt at locating an irrigated farm. The site was not desirable. It lacked all the essentials of success. So, with many homeseekers. They join the bands of men and women going West to grow up with the country. Their destination is as uncertain as the wind.

"Canvas does not hold a sadder

Deep Well Pumping For Irrigation.

The past season has demonstrated more than ever the practicability and superiority of the Pomona Deep Well Pumps. It is fully proven that it is possible to lift large quantities of water from very deep wells with a surprisingly small amount of power. It has usually been considered that a plunger pump is only good for a 35-inch stream on a lift of say 200 feet, but the Pomona Manufacturing Company have demonstrated that it is no longer necessary to use a centrifugal pump, with its wasteful usage of power, to get a large quantity of water out of the ground, as this company is manufacturing extra large size cylinders including 12, 13, 14 and 16 inches in diameter, and capable of lifting from 50 to 100 miner's inches of water. Not only that, but they are prepared to go down after it to depths of 300 and 400 feet if necessary.

They have one plant at Claremont where the water stands 390 feet below the surface and the pump has a total lift of 450 feet, delivering 45 miner's inches of water with 60 H. P. on the motor, and doing it easily. There is another plant in Ontario lifting 60 miner's inches 300 feet with a 60 H. P. engine.

The parts below the surface have been so perfected that they are perfectly reliable and are giving as little trouble as it is possible for a machine to do. Other pump makers, noting the wonderful success of the Pomona Pumps, are trying to imitate them, promising something just as good, but they are only imitators and have not the knowledge or ability to make their claims good.

The Pomona Manufacturing Company has a large plant at Pomona, the only one in Southern California, devoted almost exclusively to manufacturing Plunger Pumps. They are a reliable establishment and are here to stay, to make good their guarantees and to supply your wants in the way of extras or assistance. Their machines and apparatus have been tried out and their value fully demonstrated.

Anyone needing pumping machinery should send to them for catalogs, or visit them in person.

Would ½ More Water
With the same power from deep wells **Interest You?**
It is accomplished with the Double-Acting
"American" Deep Well Pump
It delivers full cylinder capacity both on the **Down**-stroke and the **Up**-stroke. It requires at no time more power than the up-stroke of a single-acting cylinder of the same displacement.
Send for the most complete deep well catalogue ever issued, No. 110 just off the press, mailed free.

When writing advertisers mention the Cultivator

painting than that showing the home returning of a disappointed fortune seeking family. I have seen them. Pictures of distress, broken hopes and faded lives. A large family left one of the best counties in southern Illinois and went West. All the group of nine possessed, was converted into cash. That went into the hands of a land shark in a western city to pay for a tract on which no man could make a living. After spending one season that family left.

"Could the land agent have seen the misery in that family would he have felt enough pricking of conscience to give the children money to buy clothing? No, that is not a part of the program. Had the salesman set eyes on that emaciated, half-fed, poorly clothed and heartsick wife and mother would he have contributed five dollars to a fund for taking her back home? No, such things are printed in stories, but not enacted in real life. But I have seen even worse things among disappointed homeseekers."

POWER PERMITS.

A new form of water power permit and new regulations for water power plants on the national forests were approved yesterday by the secretary of agriculture. The important changes under the new regulations are that they provide for the issuance of a preliminary permit which secures to the party making the first application protection during the time necessary to make his final surveys and procure the data for the issuance of the final permit. The new permits will terminate at the expiration of 50 years, unless revoked sooner by the secretary of agriculture, and the charge will be based upon the net horsepower capacity of the plant, beginning with a charge of 10 cents per horsepower during the first year and rising gradually 10 cents per year to $1.00 per horsepower in the tenth year, which charge will continue thereafter. Computed for the 50-year period, the charge under the new permit is about 30 per cent less than that under the old form. Provision is made for a readjustment every ten years of the factors upon which the estimated capacity of the plant is computed. It is believed that the new regulations will encourage extensive water power development in the national forests under provisions which will fully protect the interests of the people.

PROSPECTS BETTER FOR IRRIGATION BOND ISSUES.

The general outlook for the better class of irrigation bonds has greatly improved. Buyers are turning away from low-priced issues of all kinds, and while they are no less discriminating than ever, their demand is for bonds of high earning power. This is a feature of the monetary situation the world over, and all governments have had to take notice of it.

Irrigation bonds as a rule are returning 5 to 6 per cent, and it is apparent that capitalists will be insistent on at least a 6 per cent basis. At such a figure there is likely to be a good market during 1911, for money is easier, and is likely to remain so for some months to come.—Irrigation Age.

The great dam in Mokelumne river near Woodbridge, has been completed and will supply water to irrigate 60,000 acres of land in the vicinity of Woodbridge, Lodi and other fruit districts in northern San Joaquin county.

TO BE RECLAIMED.

To reclaim 15,000 acres of land in the Wood River Valley, near Klamath Falls, Ore., a levee 24 miles in length is being built by Senator Abner Weed of Siskiyou, Cal. The work is about half finished. Senator Weed owns 15,000 acres of land in the valley, between the mouth of Wood River and the mouth of Seven Mile Creek, and this levee along the lake shore is to protect these large holdings from the lake overflow in the wet seasons. The levee will serve as an embankment to keep the water from overflowing the land, and the ditch will serve as a drain for the wet land lying along it.—Irrigation Journal.

Up to the present time about 300,000 acres of land in Indian reservations have been reclaimed by irrigation works, of which amount 118,640 acres are being irrigated by Indians, and 42,080 acres by white lessees and purchasers. The area which will be irrigated when completed amounts to approximately 1,100,000 acres. The total appropriations for irrigation purposes during the past year amounted to $1,365,000. By act approved June 25, 1910, congress authorized the secretary of the interior to reserve from location, entry, sale, allotment or other appropriation any lands within Indian reservations valuable for power or reservoir sites, or which may be necessary for use in connection with any irrigation project. This authorization will be of great value in providing for and accomplishing the irrigation of arid Indian lands.—Secretary Ballinger's Report.

Fifty farmers, owning 20,000 acres of land on the Lower Eureka flats, southwest of Spokane, Washington, have formed a company to install an irrigation plant, costing $100,000. The land is too light for wheat and it is believed it can be used for alfalfa and fruit when supplied with water. Walter Reborn, city engineer of Walla Walla, and G. W. Winkle, engineer of Walla Walla county, have made surveys of the project. One plan is to convey the water from the Touchet river at Prescott by a 20-mile ditch, the other being to pump from the river at Lamar, lifting the water 200 feet to a ditch, which is to be 12 miles in length. The latter plan involves the construction of a reservoir to hold the water when the river is low.—Irrigation Journal.

The prospective home-maker of the East contemplating changing to the West should not believe all he reads or hears about the country. Richly colored prospectuses are sent out by good and bad irrigation promoters, for there are two kinds of irrigationists, even in the West. All classes get the best printing possible, becaues it pays to do so. The printers use their best paper and inks, and exercise ingenious methods of display, for the reason that it pays them to put out the best specimens of the printer's art. Yet all they print is not the truth.—Irrigation Journal.

A SLEEPY BOY.

"Up! Up, my boy, it's time to dress,"
Calls father in the morning;
And then, a second afterward,
There comes another warning.
"What! not up yet, you lazy boy?"
Says father quite severely.
"It's fifteen minutes since I called,
And breakfast's ready, nearly."
Now what I really want to know,
Is where those fifteen minutes go.

FARM LANDS FOR SALE.

160-Acre Ranch in Tulare County Cal.—2 miles from Poplar, near Portersville. All under cultivation; houses, two barns, granary and blacksmith shop. Mail delivery and telephone. Irrigating ditch running across ranch with full water right. Especially adapted to raising alfalfa, deciduous fruits and eucalyptus. Citrus fruits are grown on adjoining ranches. One mile from proposed electric railroad. Being unable to locate on this ranch I will offer it for sale at the bargain price of $55 per acre. Write for terms and further information to H. F. Stubbs, Bradshaw, Neb.

For Sale—By owner, good farm land, $50 per acre, in Merced County, 9 miles from Merced and ½ mile from station on S. P. and 4 miles from La Grande on Santa Fe. This land is a rich, sediment soil, situated in the Artesian Belt and an abundance of water is thus assured. Is level and all under cultivation. No alkali, and is suitable for figs, corn, alfalfa, beans, and all farm crops. Will subdivide in lots from 40 to 1000 acres. This land is very cheap at the price. In fact, it is only one-half the price of other land in same locality. For further particulars, call or address Paxton, 612 Lankershim Bldg., Los Angeles.

For Sale—$15,000 buys 80 acres of well improved land in Tulare Co. 45 acres in alfalfa, 9 acres in bearing Muscat vines, about 1500 one and two-year-old peach trees, 10 acres pasture land. All well fenced and cross fenced, with hog fence, big two-story barn, small house. School house near, 4½ miles southwest from court house. Plenty of water to irrigate with. Will sell as a whole or in part. Good terms. Wm. D. Green, R. R. 3, Visalia, Cal.

For Sale—A 20-acre farm for $20 cash and $20 a month; possession now; $90 to $125 per acre; your crops pay for the land. Rich, level land for alfalfa, oranges, almonds, grapes, cows, chickens; abundance of ditch water, for irrigation, for $1 an acre a year. Where else can you get this? In Oakdale Colony, near good town and railroad station, climate delightful. T. Wiesendanger, 207 S. Broadway, Los Angeles, Cal.

For Sale—Or will exchange for Southern California Apiary. Olivecrest, a two-acre country home in Sonoma County. Five-room cottage. Fifty olive trees, thirty of mixed fruit. Five large oak trees. Two wells. View of mountains and valley unsurpassed. Was summer home of an author. Two hours from San Francisco. One mile from good town. Price $2000.00. Box 725, Brawley, Cal.

For Sale—815 acres in San Luis Obispo County. A typical dairy ranch. Plenty of wood, water, irrigable land, buildings, fenced and cross fenced. Orchards, vineyards, oranges, lemons and walnuts do exceedingly well here. Forty acres of land suitable for these. Price $21 per acre. For further particulars apply to Mrs. F. A. Clink, Pozo, Cal.

For Sale—The Fresno Meadows Colony is now opened for settlement in lots of 40 acres or more with water at $50 per acre. This is an opening price and is made to induce settlement. Arrangements can be made so that the first payment will carry the deal indefinitely. Call or write at once. Green & Webb, Gen. Sales Agents, 406 Laughlin Bldg., Los Angeles. Phone A8284.

San Joaquin Valley alfalfa land for sale with railroads, schools, electric power and cheap water at hand. 40-acre tracts and up at reasonable prices. Also several large stock and alfalfa ranches with artesian water. C. H. Biggin, Pixley, Tulare Co., Cal.

Farms Wanted—Don't pay commissions. We find you direct buyer. Write, describing property, naming lowest price. We help buyers locate desirable properties free. American Investment Association, 12 Palace, Minneapolis, Minn.

Irrigated Land—The famous Gridley Colonies. Improved lands, best homeseekers' proposition in California. Write for particulars. Gridley Land Co., Gridley, Cal.

WICK'S WHITE FOWL FARM, Moorpark, Cal

MACHINERY.

ATTENTION, FARMERS!

120 Horsepower Pumping, Lighting and Power Plant, composed of two 60-horse gasoline or distillate engines, with Westinghouse generators, switchboard, circuit-breakers, storage batteries, etc.

In addition we can furnish four 20-H. P. D. C., one 10-H. P. D. C. and two 7½-H. P. D. C. Western Electric motors. All of these are in first-class condition, having been overhauled at our works.

Just the power for pumping several wells at a short distance from each other. We will sell one unit of 60 H. P.

This plant cost new $10,000, but we will sell complete for $4,000. The generators alone cost $2000. We can supply any extras as we have all the patterns of the parts. Will make prices on motors in proportion to the above.

Also one R. & V. 6-H. P. vertical gas engine, new, and one new 18-inch single-acting Addison pump head and cylinders. Price $360.00, which is 25 per cent discount on lowest purchasing price.

Do not miss this chance.

Axelson Machine Co., Wyse and Ann Sts., Los Angeles, Cal.

For Sale—Second-hand windmills, tanks, pumps, engines, farm machinery that will do the same work as new at half price. Finest and largest stock of tanks we have ever had. We are overstocked on tanks and are selling them at cut prices. Especially fine 2,000 gal. redwood tanks at $19.50. Some 8,000 and 10,000 gal. brand new, never been put up, at half price. Round stock tanks 2x8 ft. for $10. Wine tanks, water tanks, oil tanks, pickle tanks, spray tanks.

WINDMILLS
8, 10, 12 ft. sizes, complete or separate.
ENGINES

1½ H. P. Lambert and pump complete, guaranteed A1, too cheap to quote. 2 H. P. complete or separate, 4, 6, 18, 20, and 32 H. P., also many others. Blacksmith tools, grading tools, 2 horse orchard sprayer, windlass, plows, scrapers, wagons, fine $325 stanhope, swap at $100, silver mounted harness $25, light double harness nearly new cost $35 for $19.50, header, baler, mower, 25 H. P. gasoline hoist, in fact, most anything you are looking for second-hand. If we haven't it, know where you can get it. Demmitt Co., upstairs, 120 N. Main St., Los Angeles.

For Sale—9 H. P. portable gas engine on steel truck. Almost brand new. Price right. Machinery Exchange, Main & Bruno Sts., Los Angeles.

For Sale—Gasoline engines. We have the stock. If you want a second-hand engine with our guarantee for a year against all defects, see Bailie & Brandt Co., 943-945 N. Main St., Los Angeles.

For Sale—A good portable drilling rig, good for 800 ft., complete string of tools. About half its value, at $750.00. Address M. H. Magie, 1242 Harvard Blvd., Los Angeles, Cal.

For Sale—A practically new No. 2 Sharples Separator. Snap. C. P. Dandy, 421 Wilcox Bldg., Los Angeles.

Don't Put Off Painting—
It Will Prove Costly

The longer you put off painting the more oil and lead the job will take.

While you wait your buildings rot, exposed to the weather.

The cost of paint made of

"Dutch Boy Painter"

white lead and pure linseed oil is not so high as you may think.

For an average house, the cost now of this genuine old-fashioned, mixed-to-order pure white lead paint is not more than $4 or $5 greater than it used to be. Much cheaper than repair bills.

General Household Notes

AS YOU MAKE IT.

To the preacher life's a sermon,
To the joker it's a jest;
To the miser life is money,
To the loafer life is rest.

To the lawyer life's a trial,
To the poet life's a song;
To the doctor life's a patient
That needs treatment right along.

To the soldier life's a battle,
To the teacher life's a school;
Life's a "good thing" to the grafter,
It's a failure to the fool.

To the man upon the engine
Life's a long and heavy grade;
It's a gamble to the gambler,
To the merchant life is trade.

Life's a picture to the artist,
To the rascal life's a fraud;
Life perhaps is but a burden
To the man beneath the hod.

Life is lovely to the lover,
To the player life's a play;
Life may be a load of trouble
To the man upon the dray.

Life is but a long vacation
To the man who loves his work;
Life's an everlasting effort
To shun duty to the shirk.

To the heaven-blest romancer
Life's a story ever new;
Life is what we try to make it—
Brother, what is life to you?

STORY OF RAMESIS.

The Chateau de Ploerneuf was the terror of the Bretons. On passing it the peasants made the sign of the cross and murmured under their breath: "The Chateau of the Accursed!" Brambles grew about its boundary walls, which no living soul dared to pass. The valets moved about within like shadows, never raising their voices. No one ever spoke to the master.

Alone the young Comte Robert found grace before the lord of the manor, the old Duc de Kerberzoff, his uncle.

At this moment when the recital commences, Robert was at the feet of the old man, who, with livid face, glittering eyes, and marks of fear on all his features, sat in the great ducal chair, listening to what the specter of terror said to him.

By his side, upon a porphyry column, burned a small golden lamp, ornamented with precious stones, into the flames of which a tall negro poured, minute by minute, a drop of oil. In the old man's rude hand gleamed an axe; the negro would have paid with his life the least forgetfulness of his duties.

The duke was paler than usual. His long white hair clung to his brow, and from his eyes great tears rolled down upon his silver beard.

"My dear lord, are you in greater pain?" asked Robert tenderly.

The duke shuddered, listening still.

"Christmas! Christmas!" sang voices in the fields. "Christmas! Christmas-" sounded the church bells.

Then, drawing himself up, specter-like, he said:

"Listen, Robert, listen!"

For twenty years the old man had not spoken.

The sepulcral voice resounded in the great hall; the arms, struck by echo, gave out an iron plaint. The young count felt frozen with fear.

"Twenty years ago I had a son—handsome, brave and generous. He loved a young low-born girl, and wished to wed her, but I refused—I could not consent to such an outrage. My son implored me, but I remained inflexible. My blazon would have been shattered by such a shame! I was wrong, child—I was wrong! Never be arrogantly proud. It is a mortal sin!"

Sobs stifled the old duke's voice. But presently he went on:

"The girl was beautiful and virtuous. I offered her gold; she refused it. Then I had her abducted and shut up in a tower of the chateau. Months passed away. My son remained faithful to his vows, I faithful to my pride. I therefore resolved to kill the girl. To that end, I sent her secretly a message, advising her to escape. A silken ladder was conveyed to her, with minutely detailed instructions as to how she was to fasten it to her window. She prepared to fly, and then I invented an infamous trap!

"Listen, Robert—listen! I caused the stones which supported the window to be loosened, so that it should give way under her and she would be dashed upon the marble pavement of the courtyard below. It was Christmas, the night of that evil deed; and ever since I have slept in fear of God.

"That same night I was transported in dreams into an immense gallery of clouds. Vaults followed upon vaults in millions—extending, ever extending. Under these vaults hung little golden lamps, swaying gently. It would have taken years to count them. Some of them burned brightly; others were extinguished suddenly. Some shone with a violent glare; others flickered and spluttered a long while before they went out.

"Some of these lamps were guarded by angels, white and beautiful as beauty itself. Others of the lamps had angels, black, ugly and malevolent, who seemed to wait impatiently the moment when the flame should expire.

"'What does all this mean?' I asked my conductor.

"'All those lamps are human souls,' he replied. 'Those which burn so brightly are the souls of new-born infants; stainless angels guard them. Here are the souls of those who are at the age when, some think, the Spirit of Evil and the Spirit of Good contend for them; but, at the supreme moment, the last breath almost always returns to the Spirit of Good.'

"I then asked to be shown my own lamp.

"'Come with me,' said the strange being, and leading me under innumerable vaults, he made me traverse a great distance. At length, stopping me abruptly, he said: 'Behold! there is your soul!'

"I was petrified with terror. A single drop of oil remained in my lamp; and above it an angel with black wings blew upon the flame to accelerate its extinction. I was seized with dread—overtaken by cowardice—yes, cowardice!" said the duke, trembling in every limb.

"Listen, Robert, listen! Beside me burned a flame of purest light; that lamp of gold, protected by an angel with wings of spotless white. The Spirit of Evil whispered in my ear."

The old duke stopped—as if the voice were speaking to him again. His eyes became bloodshot, his hair rose on his head with horror, his teeth chattered with affright, and when he continued his voice was almost a shriek.

"I went to the lamp guarded by the

angel with the white wings, who looked at me sorrowfully; but the angel with the black wings still whispered in my ears. I saw nothing; I did not wish to see anything; I plucked a feather from the wing of the black angel and dipped it in the brightly flaming lamp and took from it the oil, drop by drop, and poured it into mine. My flame became glittering and red as blood; the other paled, but preserved still the brightness of a star. But when the drop of oil was left in it the angel that guarded it spread his white wings and would have stayed me, but an angel with pearly wings and bearing a golden sword suddenly appeared.

"'Let this human being do according to his will—God will judge him,' it said.

"I took the last drop of oil! Then fear seized me. 'What lamp is this?' I asked, pointing to the poor flame that was ready to expire, and the voice replied:

"'It is the soul of your beloved son.'

"At the same moment the clear flame of the lamp died out; the white angel took its last breath in his wings and flew away, uttering as he went with it a cry of distress. The Spirit of Evil replied with a cry of triumph.

"I awoke frozen with horror.

"In my chamber lay two bodies—crushed, unrecognizable. My son, informed by his fiancee, had tried to protect her in her flight, and my criminal snare had destroyed them both. It was Christmas, 20 years ago."

Saying this he made a sign to the negro tending the precious lamp to cease feeding its flame.

"I have made confession," he added, "and can now die, but will God forgive me?"

At that moment the bells of the chateau pealed forth and the voices of the singers in the church were heard. The doors of the great hall opened. At the back of the chapel of the old manor, resplendent with lights, the infant Jesus, lying upon his bed of straw, appeared radiant with celestial glory.

The old duke fell on his knees before the infant diety.

"Man," said the voice of the priest, "Jesus was born to suffer, and died for the redemption of sinners. You have sinned, you have suffered, you have repented—God forgives you. Your soul pass from you in peace!"

Then the old man turned his eyes toward the lamp, above which an angel with white wings was hovering. That angel he recognized—it was the guardian angel of the brilliant lamp.

The angel smiled sweetly and took within its wings the expiring flame, with which it flew heavenward.

The Duc de Kerberzoff was dead.—Sarah Bernhardt in Exchange.

When the gums are tender and bleeding, the mouth should be rinsed with warm water to which listerine has been added.

DRIED BEEF.

Seventy pounds of beef, preferably the tender or inside part of the round or thigh.

Four quarts of fine salt.

One pound of brown sugar.

One teaspoon of pulverized saltpetre.

Salt the beef by rubbing in the salt and other ingredients in a wooden tub, and let it remain in the pickle produced by the action of the salt on the meat, for eight or ten days. If the salt should all dissolve put more on (or do not put on all at the beginning, which then can be rubbed in subsequently). After thoroughly pickling, make a slit in one end or corner of the meat; through this pass a piece of stout string, or cord, then hang up to dry. A cool, dry place is to be selected for this process. Cover it with a piece of mosquito netting to keep off the flies. Smoking the meat the usual way might be done, but the result is more satisfactory without.

It is needless to add that should the quantity of meat be less or more than that mentioned above, the proportions should vary accordingly.

Pickling fish or herring can be done in the same way; some omit the saltpetre. In the case of herring, the scales are scraped off, a stout pair of scissors are used to cut off the fins and eviscerate. As soon as the entrails are taken out rub salt plentifully, until all the fish have been prepared. Allow to remain twenty-four hours, then wash thoroughly in running water. The salt will have purified the interior of the fish. Lay open part down on a board or table to drain, or else dry with a towel or cloth. Then rub in more salt in and outside and let them stand in a tub for two or three days, when the fish are to be placed where they will dry, protected from insects. After thoroughly drying, hang them in bunches, loosely, in a barrel with both ends knocked out, cover the upper end, where the fish are supported by strings or small sticks or rods. In a small furnace, pan or other receptacle build a fire, cover with damp or green wood to make as much smoke as possible, place the barrel with the suspended fish inside and let it stand for the necessary time to smoke the fish properly. When thoroughly smoked store them away in a dry place. If properly done they will keep for a long time. These are much better than the fish bought at the stores, having a peculiar flavor and taste not otherwise attainable.

The French Canadians of Louisiana prepare what they call "tassao" or "tasso," which is sun-dried beef. It is excellent, far superior to fresh beef. The process is not known to the writer, but I have understood that the meat is cut in slices and hung on clotheslines in a very hot sun. "Jerked beef" is similarly prepared, only the meat is cut into strips. "Pemmican" is beef thoroughly dried and then pulverized. This is made use of by French Canadians and others traveling in the far north.

Business

AUTOMOBILE SALES.

Millions of dollars more will be invested in automobiles during 1911 than was invested during 1910, but the total number of cars sold will not be increased.

The whole tendency of automobile sales for the coming year will be away from cars of low value and low price, and toward cars of high value and better than average price.

This statement, made today by Charles T. Jeffery, president of the Thomas B. Jeffery Company, is based upon accurate information gathered from hundreds of dealers in every nook and corner of the country and from thousands of owners and prospective buyers.

The head of the Rambler Company has just concluded a conference with fifty representatives of the Rambler metropolitan distributing and service centers. From each of these was required a careful report of sales conditions in his territory. These men represent nearly every state in the Union, from Maine to California. To the information they offered has been added that gathered from a thousand sources, with the result that the following statement has been made by Mr. Jeffery:

"The volume of sales of cars above medium price will be larger than ever before, but the total number of cars sold will not be greater. Those who have previously purchased low-priced cars have been educated up to those of better quality.

"The Middle West will take a larger volume of the output during 1911 than ever before, but while the sales of cheaper cars will be more numerous, by far the greater volume of sales will be made of those averaging about $2,000 in price. This because the farmer will be the biggest buyer, and he wants weight, capacity and power.

"The Pacific Coast, where the better class of cars have always sold easily, will buy more than ever before, as present indications are that deliveries cannot be made fast enough.

"The Northwest, where the largest sales of medium priced cars have been made this year, will take about the same number as last year. Texas will show a small increase, from present indications, while in the Central States, the bulk of the sales will be those of the better than medium cars, and to replace those of lower price.

"Our sales for the past year have increased forty per cent. The largest increase has been shown by New England and the South."

POULTRY FEEDING FOR PROFIT.

The above is the title of a very useful book which should be in the hands of every poultry raiser in California. Issued by the Coulson Poultry and Stock Food Company of Petaluma.

It contains full information on the subject of feeding, together with an analysis of the various elements essential to chicken strength. It also contains a complete list of poultry remedies, supplies, incubators, brooders, etc. Mention the Cultivator and the book will be sent by return mail, free of cost.

NEW HOME.

A fine new building has just been constructed by the Pioneer Paper Company at 247-51 South Los Angeles St., Los Angeles. This building was designed and constructed especially to meet the requirements of the paper house. Five floors and basement extending the entire length of the building. Large plate glass windows, affording ample light. The building is equipped with modern conveniences and labor-saving devices. Two elevators have been installed, also an automatic "Lowerator." The lowerator is for carrying heavy boxes and packages from the upper floors to the shipping room on the first floor. This it does with the greatest ease. The basement, which is well lighted, has a 10-foot ceiling, and is used for storing heavy wrapping papers and paper bags. A modern sprinkling system has been provided on every floor. This system is sufficient to flood the entire floor in a few minutes' time, and materially reduces the rate of insurance.

These are only hints of some of the features in this new building, which is a deserved convenience of this company which has catered to the needs of paper buyers, especially the ready roofing buyers, in this state for the past 20 years. The business has continued to grow until this structure has been made necessary. Speaking of roofing, by the way, it would be well to drop a card to the company asking for information on the subject of ready roofing.

STRIKING CATALOGUE.

The latest issued catalogue of the Petaluma Incubator Company has only fifty pages, but it sure is a most striking booklet. The cover with its "Standard of the World" is a magnificent half-tone of California's great trees and the center page is a panorama of a train loaded with redwood logs. Underneath is the statement that in the train are logs sufficient for lumber to make 3000 Model No. 91 Petaluma Incubators. The Petaluma people have made much of the redwood construction of their incubators and the splendid quality of this lumber has been one cause of the success of its machines. The booklet is well worth asking by poultry people.

SECOND-HAND PIPE.

You can frequently buy second-hand pipe which is practically as good as new at greatly reduced prices. The Pacific Pipe Company, of San Francisco, is the largest company of this kind on the coast. When the pipe is brought to the works it is thoroughly cleaned, rethreaded and dipped in asphaltum to give it resistance against the action of water and other elements with which it comes in contact. In wearing qualities it is as good as new pipe.

The company carries a large stock at all times, and any quantity of any size may be secured.

Their specialty is second-hand pipe, but they also carry boilers, centrifugal pumps, gas engines and second-hand machinery. Prices are quoted on request.

SUCCESSFUL POULTRY BREEDING.

A novel and instructive booklet is that issued by the Poultry Breeders' Supply House, 845 S. Spring St., Los Angeles. It is "What to Use for Successful Poultry Raising," and on its title page we note it is a catalogue for 1911, and the first article listed is a striking portrait of Mr. Frank J. Ironmonger, in charge, and this is no joke, for Mr. Ironmonger is at the service of poultry keepers, and that means much to their advantage. He is an old-timer, having been with the Henry Albers Company for many years and has now succeeded to the retail business. We will assure our readers that he will also succeed in this business. The booklet is well worth the asking, and it will be sent by Mr. Ironmonger if card is dropped to his address.

NEW MODEL PETALUMAS.

The Petaluma Poultry Journal has a newsy description of several new models of Petaluma Incubators, which, as it says, are the culmination of over thirty years actual manufacturing and more than forty-five years' experience in incubator building. Amongst other points mentioned which are new and valuable, we give:

"The air filter through which the fresh air is admitted to the heater has its entrance some distance away from the lamp, therefore there is no possibility of any odors of the lamp entering the egg chamber.

"The heater is built in such a manner that the copper portion with which the heat of the lamp comes in contact has been pronounced by mechanical experts and engineers on heating and ventilation, to which it has been submitted for examination, as a perfect piece of constructive work in metal; the tools for making which are the invention of the Petaluma Incubator Co., made at great cost, and there is not another set of such tools and machines in existence.

"A revelation in incubator construction, admittedly in advance of all ideas, theories and methods, the surprise of the times, the greatest invention in this line since artificial incubation was first introduced by us, yet a marvel of simplicity."

Iron rust, mildew and ink, where the stains are not large and well defined, may be removed by repeated applications of lemon juice and salt, and exposure to the sun, that potent agent for bleaching. Kerosene oil will erase fresh wagon grease, and machine oil yields to cold soapsuds.

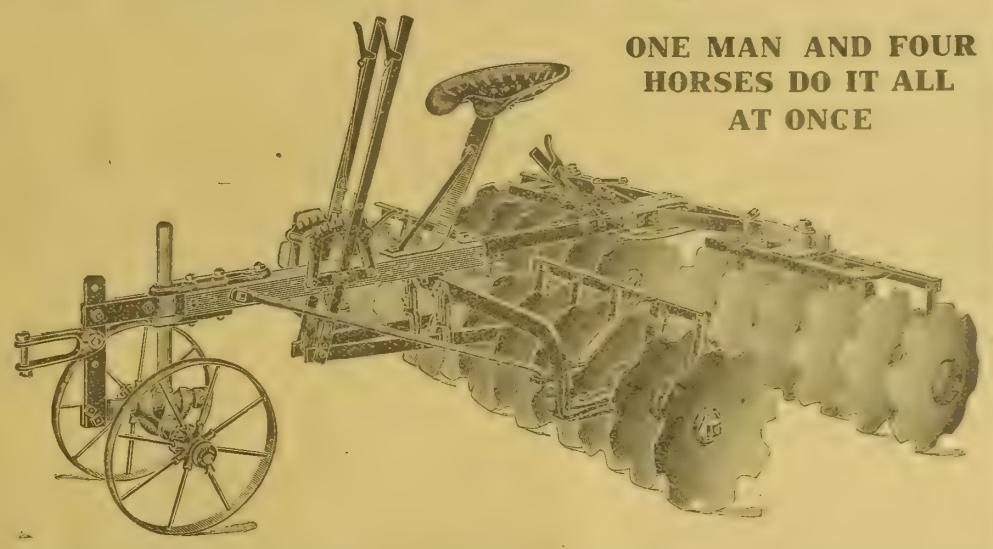
ARNOTT DOUBLE DISC HARROW

A Plow—A Disc—A Pulverizer—A Smoothing Harrow all in one

The SENSATION of the Day

Compare it Point for Point With Any Disc Harrow Made

Double Gangs
Double Cut
Double Throw
Double Levers



ONE MAN AND FOUR HORSES DO IT ALL AT ONCE

The flexibility of the **Arnott "Double-Cut"** in contrast with the stiff action of other two-way harrows is what is making it so popular. This flexibility is possible because of our Universal Joint connecting the front and rear gangs. For lack of this feature other double harrows have a good deal of side draft and will not make a square turn without digging a great hole. This can't happen on the **Arnott.** Independent front and rear levers within easy reach of rider.

Complete description mailed upon application. Write for prices

ARNOTT & COMPANY, Inc., Southwestern Gen. Agts.

112-118 South Los Angeles Street, LOS ANGELES.

All sizes in stock for immediate shipment, 4 to 10 ft. cut inclusive.

SAVE YOUR TIME WATER and GRADING BY IRRIGATING WITH AMERICAN SURFACE IRRIGATION PIPE

The **PIPE RECOMMENDED BY ALL USERS.** It is the **ONLY SCIENTIFICALLY CONSTRUCTED SURFACE IRRIGATION PIPE** on the market. **THERE'S NO ROUND SEAMS TO LEAK,** retard the flow of water or weaken the pipe. This pipe is easily handled and cheaper than flumes. It will last a life-time. For irrigating alfalfa it is the only pipe to use. We make **RIVETED PIPE AND TANKS.** Write for Illustrated Catalogue, also **SPECIAL IRRIGATION FOLDER** which may mean much to you.

American Steel Pipe & Tank Co., General Offices 342-43 Pacific Electric Bldg., **Los Angeles, Calif.**

San Francisco-Los Angeles Produce Markets

Los Angeles Market

LOS ANGELES, Feb. 1, 1911.

Butter.

Butter has declined 2½ cents, and a featureless market prevails.

Prices to trade 2½c in advance of the following Produce Exchange quotations:

Extras	32½
Firsts	30
Cooking	20

Cheese.

Local	18
Northern, fresh	17½@18
Oregon Daisy	17½@18
Domestic Swiss	20

Eggs and Poultry.

Eggs took a tumble of a cent both Monday and Tuesday, with market not strong.

Paying price f. o. b. Los Angeles is:

Local ranch candled	32
Case count buying price	28
Northern	26@30
Eastern storage	23@24
Eastern case count	19

Dealers pay for live poultry f. o. b. Los Angeles:

Hens, per lb	15@17
Roosters	9
Spring	17@21
Turkeys	21@22
Ducks	16@17
Geese	16@17
Squabs, per doz	1.75

Live Stock.

The following quotations are f. o. b. Los Angeles on all stock:

Hogs, 175 to 200 lbs	8¼
Prime steers	6
Heifers	5
Calves, per lb	6½
Sheep, ewes, per head, shorn	5.00
Lambs, per head	3.75@4.25
Wethers, shorn	5.00

Potatoes.

Wholesale prices are:

Extracted dark	5@6
Beeswax, lb	24@30

Scott, Magner & Miller say:

Arrivals of hay for the week on our market have amounted to 2,650 tons, which is a slight increase over last week's arrivals.

The market has continued along during the week in a very dull and neglected condition. Neither the dealers nor the consumers are buying to any great extent, and with the continuation of the rains during the week it has been difficult to move the hay that has been arriving with any satisfaction.

An occasional car of fancy will sell up to our topmost quotations, but the majority that has been arriving has been of the medium grades, selling at from $9.00 to $11.50 here.

There has been a little movement of hay toward interior points where the hay is required for immediate consumption, and this demand, it is hoped, may use somewhat of our surplus stock, and thereby relieve this market to that extent.

The market on alfalfa hay has continued steady, for the reason that the demand has been fairly good, and stocks of alfalfa on hand are known not to be overlarge.

We quote the wholesale prices in round lots on today's market as follows, viz.:

Fancy wheat	13.00@13.50
No. 1 wheat or wh and oat	11.50@12.00
No. 2 wheat or wh and oat	10.00@11.00
Choice tame oat	11.50@12.00
Other tame oat	9.00@10.50
Wild oat	8.00@10.00
Stock hay	6.00@7.00
Alfalfa, ton	9.00@12.00
Straw	40@50

Grain.

Wheat, No. 1	1.45@1.52½
Barley, fancy	1.12½@1.15
Barley, poor to fair	1.07½@1.12½
Oats, white	1.50@1.55
Rye, new crop	1.50@1.60
Alfalfa seed	16@18
Mustard, brown	4½

Millet	2¾
Flaxseed	5@5½
Broom corn seed, ton	23.50

Feed Stuff.

Alfalfa meal	17.00@19.50
Bran, ton	29.00@30.00
Feed cornmeal, ton	33.00@34.00
Cracked corn	33.00@34.00
Ground barley, ton	24.00@25.00
Rolled oats, ton	29.00@31.00
Middlings	34.00@36.50
Oil cake, ton	40.00@41.50
Cocoanut cake, ton	24.50@25.50
Mixed feed, ton	25.00@27.00
Shorts	29.00@31.00

Citrus Fruit Market

LOS ANGELES, Feb. 1, 1911.

The spotting or specking of fruit still continues, and unfortunately this does not show until the fruit is in the hands of the retailer. This has caused discontent and a hesitancy in buying which is affecting the market. In addition, general marketing conditions are not the best. The effect is a slight easing off in quotations in all markets. The quality of the fruit, however, excepting for its appearance on account of spots, is of the very best, and sizes are running exceptionally good. Shipments are held down to 75 to 150 cars daily. The 200 mark will probably not be reached until March.

The lemon market is exceptionally strong, and all offerings are accepted freely. Prevailing price is $3.75 to $4.00, Eastern points.

Shipments.

Shipments of oranges to date since November 1, 1910: 6,691 cars, lemons 1,059, total citrus fruits 7,750. To same date last season, oranges 3,816, lemons 991, total 4,807.

NEW YORK, Monday, Jan. 30.—Thirty-nine cars navels, one mixed car and two cars lemons sold. Market lower on navels, strong on lemons.

Triangle Trip

OVER THE

Northwestern Pacific Railroad

One of the most delightful scenic One-day jaunts in America
150 Miles of Mountain and Redwood Forest Scenery, a Boat Ride on San Francisco Bay and by Rail Along the Russian River.

Leave San Francisco 7:45 A. M. daily except Sunday, and 8:45 A. M. Sunday only, by boat across the Bay of San Francisco, in full view of the Golden Gate to Sausalito (the Sorrento of America). Thence via picturesque San Rafael and thriving Petaluma (home of the chicken industry), through Sonoma Valley to Santa Rosa and Fulton. From Fulton, through magnificent mountain scenery and redwood forests and along Russian River, to Monte Rio. Return is made along the coast, passing Tomales Bay, Point Reyes, San Anselmo, etc., to Sausalito, arriving at San Francisco 6:35 P. M. daily except Sunday, and 7:05 P. M. Sunday only the same evening.

If preferred, trip can be reversed, leaving San Francisco at 8:15 A. M. via the coast to Monte Rio and returning along the river and through the valleys, arriving at San Francisco 6:35 P. M. daily except Sunday and 7:35 P. M. Sunday the same evening.

Round Trip Fare for Triangle Trip, $2.80 except on Fridays or Saturdays, it is $2.50 and on Sundays only $2.20.

Tickets on sale at 874 Market Street (Flood Bldg.) and Sausalito Ferry Ticket Office.

LOS ANGELES FEBRUARY 9, 1911 SAN FRANCISCO

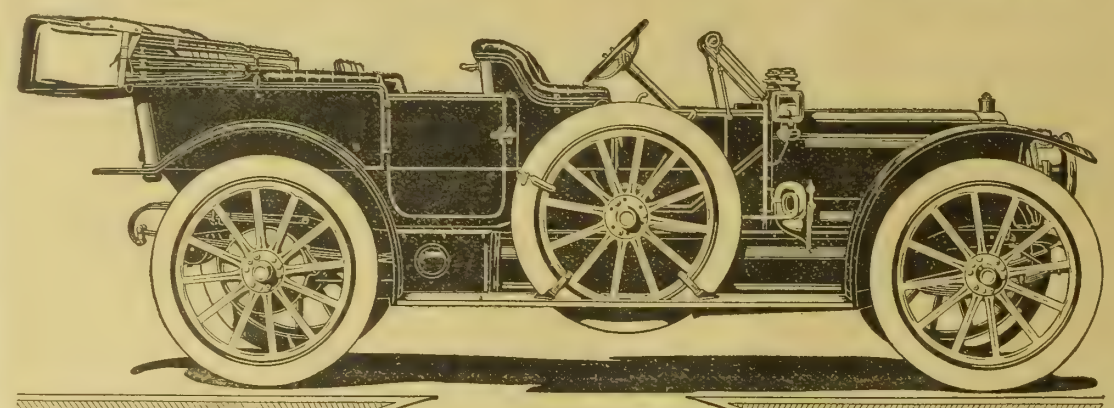
EUCALYPTUS GLOBULUS—THE BLUE GUM AS A TIMBER TREE IN CALIFORNIA.

The Popular Blue Gum—Eucalyptus globulus.

Of all the trees which have changed the landscape in California, none have the marked effect of the blue gum. The ranges of many hills are topped with this magnificent tree silhouetted against the sky line. The natural growth of this species is erect, though many individual trees are branched with open crowns. Those planted in the open field are more likely to branch and show larger tops than in compact plantings. When planted close together the best timber is secured, especially where designed for poles. The bark of the old trees is persistent, though all the younger trees exhibit the characteristic flaking off, showing bright clean trunk. We are glad to show herewith a typical California blue gum-plantation.

It is said by Baron Von Mueller that "Of the more than one thousand different species of trees indigenous to Australia, Eucalyptus globulus takes the first position in importance; also among its own kind it is the prince of eucalypts. It is the third tallest tree of the species of eucalyptus, its height in Australia ranging from 200 to 300 feet." In this state trees of the age of 30 years have attained a height of 150 feet, and a diameter sometimes as great as six feet. In the city of Pasadena is one tree 25 years old over five feet in diameter. It has been known to attain a height of 75 feet in ten years. McClatchie in his "Eucalyptus Cultivated in the United States" says: "It is without doubt the fastest growing tree in the world: It is friendly to new conditions, and taking all its characteristics into consideration it is the best all around eucalyptus. It has been more extensively planted throughout the world than any other eucalyptus, probably more extensively than all others combined."

Rambler Motor Cars



Rambler Sixty-five Forty-inch Wheels

RAMBLER big wheels and tires are a great advantage in city as well as in country driving. They not only afford added comfort, but tests have shown that tires even an inch larger in diameter and half an inch greater in width will last twice as long. Small wheels drop into the holes in the roadway, adding greatly to the discomfort and wear on tires. Big wheels and tires glide lightly over depressions, providing wide cushioning surface for comfort and tire economy. This advantage is only one of many enjoyed by Rambler owners—features of quality, comfort, safety and convenience. The Offset Crank Shaft makes possible slow driving in crowded traffic, and climbing hills easy. The Straight Line Drive saves power, the Spare Wheel saves tire worry, Rambler brakes provide complete safety, and Rambler service assures satisfaction.

The Thomas B. Jeffery Company
Main Office and Factory, Kenosha, Wisconsin
Branches: Boston, Chicago, Milwaukee, Cleveland, San Francisco, New York.

A telephone message to the nearest Rambler representative will bring this car to your door for inspection. The new catalogue is ready. Send for it.

A Pest of Deciduous Trees

Discovery by E. O. Essig, Horticultural Commissioner of Ventura County, of a New Mealy Bug Infesting Walnuts, Pears and Apples.—May Prove Serious Menace

By Courtesy of Pomona Journal of Entomology.

Among other things that a systematic tree-to-tree inspection has revealed in Ventura county, is a mealy bug infesting walnut, apple and pear trees. At first this insect was thought to be the long-tailed variety, Pseudococcus longispinus (Targ.) because of its anal appendages, which are often nearly as long as the body. A great deal of excitement was caused among the walnut and citrus growers at this discovery, for it was feared that the citrus pest had now become spread over the entire orchard district of the county. A hasty inspection of all walnut and adjoining citrus orchards followed with marked results. The inspection showed that practically every walnut orchard in the county was infested with this mealy bug, but never in great or damaging numbers; and in only one case was a mealy bug found on a citrus tree in an adjoining orchard and this was evidently not the species now being described. The following field observations proved conclusively that the new mealy bug was not P. Longispinus.

1. Its anal appendages seldom exceed two-thirds the length of the insect body, and are never longer than the body, while in the long-tailed variety the anal appendages are much longer than the body.

2. The young are hatched from loose-egg masses much like those of P. citri, while the young of P. longispinus are born alive.

3. In no case did we find this species on citrus trees, though it occurred in many orchards adjoining citrus groves. In the laboratory the live individuals, as well as the eggs, were placed upon growing citrus trees. In some cases the adults deposited their eggs before they died, while others deserted the trees. The young, as rapidly as they hatched from the eggs, crawled over the trees and the barrel, in which the tree grew, and soon died. No individual was observed to attack the foliage or branches at any time. On a walnut tree, in the same room, other individuals multiplied readily, showing that conditions were not abnormal where the experiment was being conducted.

Microscopical study revealed many other differences which are given in the description of the species further on.

The fact that it had such long anal appendages led to the decision that it was not P. citri Risso, but was somewhat of an intermediate form between Pseudococcus citri and P. longispinus. Its feeding habits (it was usually found feeding only upon the new bark formed around cracks or wounds on the tree trunks) led to the belief that it was the elder form of P. obscurus. Microscopical comparisons prove them to be identical, but distinct from Pseudococcus obscurus Essig, which was described from Opuntia. At the time of the original description, the limited supply of both forms made it impossible to separate them as I have now done. At that time, however, it did seem very improbable that the same species found on the roots of Opuntia, at Los Angeles, could be synonymous with a species found working on the new bark of Sambucus glauca (Elder) at Santa Paula, 60 miles away. Even yet the supply of Opuntia form is so limited as to make good comparisons impossible, but the accompanying drawings of the legs and antennae bring out the main characteristics of the two forms.

At the same time that this insect was found were found many individuals working similarly upon the oak trees. This mealy bug was described as Pseudococcus agrifoliae Essig and is evidently distinct from Pseudococcus quercus Ehr. Thinking that perhaps the new mealy bug found upon

FIGURE 2. PSEUDOCOCCUS BAKERI ON BARK OF WALNUT.

Facts Regarding the Lemon

A Letter Written by G. Harold Powell to Senator Flint and by Him Used as a part of his Speech in the U. S. Senate and Now Part of the Congressional Records.

Referring to our conversation in Washington in December in regard to the recent progress that has been made in the lemon industry in California, I have met a large number of growers and have seen many of the lemon-growing regions since reaching the state. It has been two years since I have given much attention to the industry. The lemon business appears to have taken on new life and the acreage is increasing at the present time. It is estimated that 3380 acres have been planted in the last two years, and at least 5000 acres will be planted this spring. A detailed survey of the lemon-growing counties has recently been made to determine the amount of available land adapted to lemon growing on which water is already developed or on which it can be developed. You will probably be surprised, as I have been, to learn that there are at least 56,000 acres in the counties south of the Tehachapi and exclusive of the Imperial Valley that are not now planted with fruit of any kind and which are adapted to lemon culture. There are at least 800 acres in San Diego, and several thousand may be developed in that county in the next few years; 1000 in Santa Barbara; 500 in Riverside; 2000 in San Bernardino; 10,000 in Orange; 10,000 in Los Angeles, and 20,000 in Ventura counties. There are now 18,000 acres of bearing lemons in the state. The present acreage, together with the trees to be planted this spring and the available acreage that will soon be planted if the conditions surrounding the industry remain settled and stable, will supply the entire American demand and leave a surplus of lemons for export. There is a big contrast between the feeling of the growers, as I find it now, and the feeling that existed in 1904 to 1906, when half a million bearing trees were either dug up or were budded over to oranges on account of the depressed condition of the industry. The California grower has set out to furnish the entire American supply of lemons.

There is practically an unlimited acreage that could be planted to lemons in Tulare county, but the crop in that part of the state matures largely in the fall. Under these conditions an extensive planting is not likely to follow. Two hundred acres have been planted in Tulare county in the last two years and seven hundred acres will be planted this spring. There are not less than five hundred bearing acres in the county at the present time. I am mentioning the Tulare county plantings especially, as they will have an important influence on the future fall prices of lemons. There is a natural shortage in the lemon supply for a short time in the fall. The California crop is light at that period. The Sicilian crop has not begun to move freely and the importation of the foreign fruit is sometimes regulated to create an unusually high price for a few shipments. Such a condition apparently occurred in October in 1910, when the New York market was kept comparatively bare of foreign fruit for two weeks in order to create an abnormal price. According to the records of the New York Fruit Exchange there were approximately 50,000 boxes of foreign lemons afloat or in the port of New York unsold September 23d; 33,700 September 30th; 23,000 October 7th. The exports from Italy, or the number reported due in New York, were then held back for two weeks. On October 14th there were only 6875 boxes and 5650 on October 21st reported by the importers either afloat or unsold in New York. One week later, October 28th, 50,800 boxes had been liberated from Italy or were in New York for sale, and on November 18th, 81,650 boxes were afloat or for sale in port. The following statement shows the approximate number of boxes of lemons afloat or in the port of New York from September 23d to November 18th for the years 1906 to 1910 inclusive.

Foreign Lemons Reported Afloat and in the Port of New York Unsold.

	1910	1909	1908	1907	1906
September 23d	49,900	38,800	22,700	51,600	32,700
September 30th	33,725	29,950	26,000	48,300	42,750

During the artificial shortage created in October 1910 by the manipulation of imports one carload of California lemons sold for $6 to $12 a box in New York. As soon as this sale was accomplished a large foreign supply was liberated, the price fell within a few days to the usual figure for that time of the year and this carload and the small receipts were used to show that the duty on lemons restricts importations and forces the consumer to pay an abnormal price for the fruit.

As a good deal has been said about this carload I think you might be interested to know that similar high prices have been obtained on foreign fruit at some period in nearly every year at least since 1885. According to the New York Journal of Commerce foreign lemons sold in New York for

LARGEST CITRUS NURSERIES IN THE WORLD

Parties contemplating the planting of citrus groves this coming spring will do well to send for our prices soon, as there will evidently be a shortage of strictly first class stock. Write today for particulars, or, better still, pay us a visit so that we may be able to show you just what we have.

Our finely illustrated booklet, "Citrus Fruits," covering the industry from the seed to the market, mailed to any address on receipt of 25c in stamps.

NITRATE OF SODA

We are prepared to furnish Nitrate of Soda at the lowest market price, and will be pleased to quote prices and furnish literature to any one interested, on application. Advise us what crops you are interested in.

NITRATE AGENCIES COMPANY
W. S. SPARR, Agent, 321 Stimson Block, Los Angeles

$10.62 per box in July in 1885; $9.50 in October, 1886; $7.50 in June, October and November, 1888; $8.75 in October, 1889; $10.37 in July, 1890, and several times above $9.00 in the same month, and $8.87 in October; $9.50 in August, 1892; $12.50, $11.75 and many times above $9.00 in September and October, 1895; $10.50 and several times above $9.00 in October, 1898. I could cite many similar high prices during the following years. Now when the Tulare county fruit comes into bearing in a few years the American public will be able to depend on a uniform domestic supply in the fall, and the abnormally high prices that have been created artificially for speculation and spectacular purposes will be a thing of the past.

There is promise of the largest lemon crop on record in California this year. It is estimated that the yield will reach seven thousand carloads or over. There is a great deal of attention being given to improving the methods of handling the lemon in the fields and packing houses. It is the most difficult fruit in California to produce and market. The United States Department of Agriculture and the University of California have co-operated with the industry for several years and are helping to solve some of the difficulties that the growers and shippers had not been able to meet alone. There are many problems still to be worked out, soil difficulties to be investigated and insect and fungous pests to conquer. The largest average yield attained in the state as a whole hardly exceeds one-third of a carload, or less than 9000 pounds, of fruit per acre for the 18,000 acres of bearing groves. There are some groves that produce a carload or more per acre, just as there unusual surgeons, lawyers and business men who stand head and shoulders above the average man in the same profession. The increase in the difficulties of production and the decrease in productiveness of many of the bearing groves have caused some apprehension as to the future of the industry. The State University recently brought two of the most distinguished soil experts in America to California to help the growers solve their difficulties, and two large conventions of fruit growers have recently appealed to the federal and to the state governments to furnish investigators and funds to co-operate with the industry in working out these troubles.

The industry is awaiting with great interest the outcome of the investigations that have been made by the Honorable Secretary of the Treasury of the effect of the present regulations in determining the decay in imports of lemons. The industry here feels that it may have been subjected to unfair competition under the present regulations and that the importer has had an undue advantage for years past by securing an excessive allowance for decay. This is a vital matter to the California lemon grower. The imports of lemons into New York have not decreased recently as the importers claimed they would when the tariff bill was under discussion. According to the records of the New York Fruit Exchange there was a difference of less than 1000 boxes of lemons in the total receipts in New York in the two years ending November 1st, 1909 and 1910. The tariff act became effective August 5th, 1909. The receipts of forein lemons into New York from November 1st, 1908 to August 1st, 1909, amounted to 1,335,275 boxes. The imports from November 1st, 1909, to August 1st, 1910, including nine months after the tariff became effective, amounted to 1,439,850 boxes, or 104,575 boxes more than during the corresponding nine months in the year preceding the time when the act became effective. The total imports of lemons into the United States for the year beginning July 1st, 1908, and ending June 30th, 1909, were approximately 135,000,000 pounds. The imports for the year beginning July 1st, 1909, and ending June 30th, 1910, were approximately 160,000,000 pounds, or 25,000,000 pounds more during the year after the tariff became effective. As long as these heavy importations continue the domestic producer feels that no governmental regulation should be allowed to stand when it is found that through its enforcement it works to the disadvantage of the domestic producer.

CITRUS FAIR PREMIUMS.

The rules governing the entrance of exhibits and premium list have been announced by the directors of the Cloverdale Fair Association, for the Citrus Fair to be held February 21 to 25, inclusive, at the association's fine building, erected just before the fair last year. The list follows:

Class A—Most elaborate display of citrus products. First $75, second $50, third $40, fourth $35, fifth $30, sixth $25, seventh $20, eighth $15, ninth $10, tenth $10, eleventh $10, twelfth $10, thirteenth $10, fourteenth $10, fifteenth $10.

Class B—Most elaborate display of citrus products, juvenile: First $10, second $5, third $2.50, fourth $1.50, fifth $1.

Class C—Best fruit in quantities, one box or more: Best Washington Navels $2.50, second $1.50; best Japanese $2, second $1, best lemons $2.50, seconds $1.50.

Class D—Best fruit in small quantities: Best Washington Navels, ten boxes or more, $10, second $5; best 24 Japanese $1.50, second $1; best Villa Franca lemons $1.50, second $1, best 24 Sicily lemons $1.50, second $1; best 24 Lisbon lemons $1.50,. second $1; best 24 pomelos $1.50, second $1; best 24 citrons $1.50, second $1; best 24 Ponderosa lemons $1.50, second $1.

Class E—Best display of greatest variety of citrus fruit grown by exhibitor: First $4, second $2.

Class F—Best exhibit of canned fruit, put up in glass, by exhibitor: First $5, second $2.50.

Class G—Dried fruits and nuts: Best general display dried fruits $2.50, second $1; best display of dried prunes $2, second $1; best display softshell walnuts $1; best display of softshell almonds $1.

Class H—Olives and olive oil: Best pickled olives $2.50, second $1; best olive oil $2.50, second $1.

Class I—Jellies and marmalades in glass, put up by exhibitor: Best jellies $5, second $2.50; best marmalade $5, second $2.50.

Class J—Best exhibit of wine, consisting of not less than 150 bottles, artistically arranged: First $20, second $10.

Class K—Best exhibit of apples, not less than ten boxes: First $10, second $5.

Class L—Best exhibit of apples in lots of 24: First $2.50; second $1.50.

Class M—Art exhibit under direction of committee.

Class N (Special)—Cut flowers and plants in pots.

Rule 1—All exhibits must be in place by 12 m. on first day of fair.

Rule 2—Exhibits must be numbered

and entered for competition under particular classes to which they belong.

Rule 3—No exhibit can enter more than one class, nor compete for more than one prize.

Rule 4—Space for exhibits under direction of the director general. However, all large and effective designs are not permissible of entrance to pavilion.

Rule 6—All the north of bay counties, Napa, Marin, Sonoma, Mendocino, Lake and Humboldt, are entitled to enter for premiums.—Santa Rosa Republican.

NITRATE OF SODA AGAIN.

By R. R. Snowden.

In view of the discussion of the effects of nitrate of soda on the soil in a recent issue, the following might interest your readers:

The consumption of nitrate of soda in the world increased more than 85 per cent for the year ending June 30, 1910, over the preceding twelve months. Increase during the same period was observed in nearly every country, including Great Britain, Germany, Belgium, Holland, Italy, India, Australia, China, Japan, Sandwich Islands, Egypt, Brazil, Mexico and others, that in the United States being 58 per cent. On the Pacific Coast and in the Hawaiian Islands the increased use for agricultural purposes for 1910 over 1909 was 12.8 per cent.

There is no question but that the facts demonstrated in Southern California should outweigh with the growers here the experience in one isolated spot across the Atlantic, or the theoretical deductions of one not familiar with conditions here. Notwithstanding the thousands of tons of nitrate of soda used in the orchards and farms of California, not one instance can be shown where it has produced black alkali in the soil where used in conjunction with superphosphate.

A prominent grower, who had no intention whatever of boosting nitrate, said in a letter to the writer that after thirty-five years of cultivaion "The grove and trees are in good condition and production"; also "This grove has had large applications of nitrate of soda, probably a total of 5,000 pounds or more per acre, in the last fifteen years." Analysis of the upper soil shows not a trace of black alkali, where it would be found if there at all.

In view of the enormous profits derived from the use of nitrate of soda each year in the vegetable and fruit industries, and the universal freedom from injurious effects noted, it would be simple folly to curtail its use until some real reason for doing so is presented.

A WORLD-WIDE TOURIST.

"The California prune is the greatest tourist in the world," remarked Brown, sitting at the family breakfast table and glancing enviously at his valise, all covered with pasters of European hotels and steamship lines.

"California prunes were on the menu cards of the dining cars from Oakland Pier to New York, and on the cards of all the leading hotels of Chicago, Washington and New York. I had them every morning for breakfast on the big ocean liner all the way across the Atlantic, and when I breakfasted at the Cecil, in London, the first and most conspicuous thing on the bill of fare was 'California Prunes.'"

"California prunes in London!" ejaculated Mrs. Brown, with surprise. "How on earth do you suppose they got there? Why, that is almost one-third of the distance around the world."

"Yes, it's a long distance from here, and, moreover, you may get a dish of them in London as cheaply as in San Francisco."

"But, my dear, I have heard you say the railroads charged such high rates that the producers couldn't afford to ship their stuff farther than a woman with a hobble skirt could make in three jumps."

"Yes, from a mouse."

"You didn't say anything about a mouse."

"Well, I meant to. It makes some difference what a woman is jumping from, at, or about. Bill Jones' wife jumped from a mouse the other day, and Bill says she circled the room three times every time she jumped."

"But there is a 7,000-mile gap between London and San Francisco."

Perhaps my comparison was rather ridiculous. When I was a boy, and anything went wrong, I whipped my dog. Men are only boys grown tall, and when we grow up, instead of whipping the dog, we whip the railroads. But I will admit that when I can go 7,000 miles away, across the Atlantic, and buy a dish of California prunes for breakfast, in London, Berlin and Paris, as cheaply as in San Francisco or Los Angeles, freight rates haven't much to do with the price or cost of an article. I think, perhaps, if the curtain was pulled aside on the fellows who are howling about freight rates, it would be found that they are doing it to cover up something else."

"But you howled as much as anybody."

"If I didn't, the fellow who paid me a profit of $7 on a suit of clothes would butt in and howl, too, but against me. I beat him to it, and he is satisfied to hear me cuss the railroads. It's an easy and quick way out of it, you know, and it's a scheme that works fine."

"But is it honest?"

"Please do not discuss a dealer's profits and moral ethics at the same time. They don't blend well."

"But honesty is the best policy."

'See here, give me something from Bacon, or Shakespeare, or Bill Nye, but don't spring something that somebody said or concluded after he got caught. Besides, you are leading me away from the original subject. I was talking about California prunes, and what I wanted to remark was that as world-wide tourists and globe-trotters they take the blue ribbon."

WHITE FLY FUNGUS FROM INDIA.

By H. S. Fawcett, of the Florida Experiment Station.

A few days ago specimens of a fungus attacking whitefly were received from Mr. R. S. Woglum, from Saharanpur, India. A microscopical examination showed that these specimens belong to the same species as the Brown fungus, Aegerita webberii, now common in many sections of Florida on whitefly. In regard to this fungus Mr. Woglum writes from Saharanpur, India, under date of Nov. 4, 1910, "The fungus is doing splendid work here in many citrus trees, its efficiency being most apparent on trees in protected situations where an atmosphere of dampness is longest retained."

The finding of the Brown fungus in India is of much interest since it indicates that this fungus probably came to this country with the white-

$1.50 House Dress of Checked Percale **$1.00**

Postage Prepaid by Us

No. 21A12 "What would the material alone cost?" It would cost you $1.00, Madam, to say nothing of the making. The regular price of a house dress of this qualtity could never be less than $1.50—this special price of $1.00 is simply to acquaint you with "NATIONAL" values.

This one-piece dress is made of Checked Percale, and, first of all, it is made of excellent quality material that will launder well and wear splendidly. The front of the waist, where the closing is effected, has plaits at each shoulder stitched to yoke depth, which gives the necessary fullness to the model. The jaunty turned-down collar, the breast pocket and the buttoned cuffs that fasten the full-length sleeves are made of plain color material. A belt of the material joins the waist to the skirt, which closes at the left side front with pearl buttons. Skirt length about 40 inches. **Colors:** Blue and White check; or Black and White check.

Sizes: 32 to 44 bust.

It is a very easy thing to order this house dress. Just put a one dollar bill in an envelope and **state the size and color desired.** We will send the dress to you at our risk of your being pleased.

Special friend-making price, **$1.00.**

This Spring Style Book is yours Free

Spring styles are greatly changed—are radically new and most delightful. Never has style news been so interesting, fashions so pleasing, and never has such a fascinating Style Book been published as this one reserved for *you*.

This Book is the wonder of the Fashion World — America's Style Authority—the great "NATIONAL" Style Book, 224 pages, filled with beautiful fashion plates of all kinds of wearing apparel for Women, Misses and Children at money-saving prices.

Now here is your part. We very much want you to have this book. We have reserved it for you, but—we need your name and address. So now send us your request for this Style Book. **It will be sent you Free.**

fly on importations of citrus from the East.

The Brown fungus was first discovered in Florida in 1896 in the Viser grove, Manatee, by H. J. Webber, who was at that time making some investigations of the whitefly. It is interesting to note what Webber says in regard to the first discovery and spread of this fungus.

"In March, 1896, it was found to be abundant over a large portion of the Viser grove of 5 acres. Many trees, however, did not contain a trace of it. A very careful search was made at this time in adjoining groves and other groves in this vicinity, but no trace of the fungus could be found. At this time the grove was in very bad condition; scores of living larvae of the whitefly could be found on almost every leaf in it and the sooty mold was very abundant. In December, 1896, the grove was again carefully examined, and the fungus found to have spread with surprising rapidity. An examination developed no living specimens of the whitefly anywhere in the grove. The fruit, which for several years previous had been very black with the sooty mold, was examined after it was picked and was found to be bright and therefore requiring no washing. The new growth, which had formed during the latter part of the summer, remained bright and almost entirely uninfected with the whitefly. The same growth in other groves in the vicinity infected with the whitefly was found to be abundantly infested with the larvae and covered with sooty mold."

Although a careful search was made by Dr. Webber for the spores of this fungus at different seasons of the year during 1896 and 1897 no spores were found, and therefore the relationship of the fungus remains unknown. It was not until 1909 that the fungus was classified and received its specific name.

About four years ago the writer noticed that on the upper side of the leaves which contained Brown fungus on the lower side, there was something that looked to the unaided eye like reddish-brown dust. On examination with the lens this proved to be a little cluster of spores. Since they were on the upper surface and the Brown fungus pustules were on the lower surface, it was only after considerable study and experimenting that it could be proved beyond doubt they were the real spores of the Brown fungus and not spores of some other fungus. The identity of the spores was finally proved by picking a lot of the clusters off one by one under the microscope, and then placing them near healthy larvae of whitefly. It was found that in 16 days pustules of Brown fungus developed upon these larvae so treated while none could be found within a distance of 1½ miles from those inoculated. The way in which this fungus develops is curious and interesting. The spore germinates and sends out a jelly-filled tube comparable in form to a rubber hose, but so small that 44000 of them could lie side by side in the distance of one inch. This tube pierces the whitefly larvae, lengthens and branches many times as it grows into the vitals of the insect. Having killed the insect, it feeds upon the dead body and increases in size till the brown pustule is formed. At this stage there are still no spores. From the pustule thus formed there grow out long colorless fungal tubes that extend over the surface of the leaf attacking every larva in their path. These finally grow around the dge of the leaf and pass to the upper surface. It is on the upper surface of the leaves that the spore-clusters are usually born. When in large quantities they give the appearance of reddish dust and may be seen at some distance. Under the microscope these spore-clusters are seen to have appendages or arms, that presumably help them to cling to objects. The cells of the clusters are inflated. When once detached the clusters blow about on smooth suffaces, with the least motion of the air, but on alighting on another leaf or slightly rough surface they tend to hold fast to it. Their lightness probably enabled them to be carried by the wind and the appendages enable them to remain attached when striking another surface such as a leaf or branch. It is not necessary to speak of the economic importance of this fungus and the methods now being used by growers to introduce it into groves where conditions are favorable for its spread.—Florida Fruit and Produce News.

LIME IN ORANGE ORCHARDS.

Will lime be good to use in an orange orchard with commercial fertilizer and stable manure? Trees are beginning to show mottle leaf and the soil is heavy adobe in nature. If lime is beneficial, what form is best, and when should it be used? How much per acre? Will gypsum answer the same purpose as lime? Am now applying ten cubic feet of stable manure and ten pounds of commercial fertilizer to the tree.—R. C. H., Riverside.

The lime should not be applied until the fertilizer is worked into the soil. It may be applied at the rate of 500 pounds or even as much as a ton to the acre. Air slaked lime is preferred. Freshly burnt lime should not be used because it is too caustic. It is possible the application of lime will aid in reducing the mottle leaf. Surely on a heavy soil it will benefit the mechanical condition. Gypsum would not answer the same purpose as lime.

FERTILIZER FOR WALNUTS.

What is the best commercial fertilizer for walnut orchard? I want something which will act more quickly than barnyard manure. Would there be any advantage in drilling in wheat and barley at this time and plowing under in April, or is there a better cover crop which could be planted now? Soil is a heavy loam.—S. G. W., Pomona.

A fertilizer rich in phosphoric acid should be applied to the walnut grove. Rock phosphate is perhaps more largely used than any other one fertilizer, but of course that would not be complete. Perhaps until you understand the needs of your soil the complete commercial fertilizer would be best. If you wish to investigate as to best results secured with greatest economy, you could fertilize different patches and watch results. The quickest acting fertilizer is, of course, nitrate of soda. That with your superphosphate would perhaps answer for the first year's application.

The benefits derived from drilling in any cover crop now would not pay for the investment. Planting of seed for cover crops should be as early as possible after the nuts are off. To add humus to the soil now the only satisfactory way would be by the application of barnyard manure. The fertilizer could be applied at once unless it be the nitrate of soda, which should be applied later when the trees are beginning to grow.

A PEST OF DECIDUOUS TREES.

Continued from Page 163.

the elder might be synonymous with the species described by Mr. Ehrhorn, and not having a mounted specimen of P. quercus, I sent several slides to Mr. Ehrhorn asking him if it was the one which he described from the oak. This is a copy of his letter: I have examined your specimens with the type of P. quercus and I find that the antennae are quite different, the joints being of a different shape. The derm around the anal ring contains many more glands in quercus and the marginal spines are stouter. In your species the antennae are more hairy, so are the legs and the trochanter has a much stouter bristle. Your species is surely not P. quercus. I have no idea what it is and am sorry that I cannot help you in the matter. It will probably prove a new species.—Edw M. Ehrhorn, Superintendent of Entomology, Honolulu.

The species is, therefore, named bakeri in honor of Prof. C. F. Baker, of Pomona College, who has aided me more in my entomological work than has any one else.

moved around these cracks and wounds, the mealy bugs were exposed in rather limited numbers, but scattered over quite a large area of the tree. In all cases they appeared to be feeding only upon the new formed

Figure 2. Pseudococcus bakeri on bark of walnut.

bark, or cambium layer, around the cracks and wounds, and were more or less concealed from view by the rough outer bark. A few were observed crawling on the outer bark, as if in search of a suitable resting place, but none were found upon the foliage of the elder trees. It is very probable that this is the native host plant, and it migrated from this to the deciduous fruit and walnut trees in the surrounding neighborhood.

Walnut (Juglans regia). This pest (if it may be called a pest) has been found more extensively distributed upon the walnut trees than upon any other host plant. Its work is the same upon the walnut as on the elder, but during the months of August and September, it was also found feeding upon the stems of growing nuts, but never in any alarming numbers. It is more

FIGURE 1. PSEUDOCOCCUS BAKERI AND OBSCURUS. A, B, C, E. bakeri; D, obscurus.

Description of Pseudococcus bakeri, n. sp.

Adult Female. (Fig. 1) The general shape of the adult female is rounded oval. Length of body 4 to 6 mm., width 2 to 3 mm. The covering consists of a rather thick white, powdery way which hides the dark body, but which is not thick enough to conceal the distinct body segmentation.

Figure 1. Pseudococcus bakeri and obscurus. A, B, C, E, bakeri; D, obscurus.

* * * *

(The technical description parts made by Mr. Essig are omitted and may be seen in the Pomona Journal of Entomology.)

* * * *

The eggs are oval in shape, smooth, lemon yellow to amber in color. Length 5 mm., diameter about one-half the length.

They are deposited in masses similar to those of the citrus mealy bug, and are located in cracks, and wounds of the tree where they may be hidden under the rough outer bark. (Fig. 2.)

Host Plants.

Elder (Sambucus glauca Nutt). This mealy bug was first observed upon the elder trees growing in the "washes" near Santa Paula, Cal. Its presence was first discovered by the aid of ants, which appeared in large numbers in the cracks and wounds of the trees. When the rough exterior bark was removed around these cracks and wounds, the mealy bugs were exposed in rather limited numbers, but scattered over quite a large area of the tree. In all cases they appeared to be feeding only upon the new formed bark, or cambium layer, around the cracks and wounds, and were more or less concealed from view by the rough outer bark. A few were observed crawling on the outer bark, as if in search of a suitable resting place, but none were found upon the foliage of the elder trees. It is very probable that this is the native host plant, and it migrated from this to the deciduous fruit and walnut trees in the surrounding neighborhood.

readily found by watching the ants than by any damage which it does to the tree, or by its numbers as is the case with most of the mealy bugs.

The inspection which was made generally over the County of Ventura, showed this mealy bug on the walnut trees at Ventura, Saticoy and the entire district around Santa Paula on both sides of the Santa Clara river. It appeared in the greatest numbers in a small orchard near Santa Paula, but here it existed in very limited numbers. Apparently it exists only upon old trees in the older orchards, which might have been set out when much of the surrounding territory was still growing elder trees and the orchards became infested years ago. This would seem to indicate that the insect is slow to breed and not very destructive, or that it is held down by native insects.

Apple (Pyrus malus). On apple trees badly infested with Woolly Aphis (Schizoneura lanigera) were found mealy bugs in considerable numbers associated with this plant louse. The Woolly Aphis had caused many of the burls or knots on the limbs and suckers, as well as the crown roots of the tree. The new bark which endeavored to heal over these wounds afforded the desirable conditions for this mealy bug and in every case it was found feeding upon the new bark so exposed. It was especially abundant upon the

The Largest and Lowest Priced Furniture House in Western America.

Our immense store—150,000 square feet of floor space—and our immense reserve warehouse—the largest in the west—contain the largest stock of household and office furnishings carried in any establishment west of the Mississippi River. Furniture, pianos, carpets, rugs, draperies, linens, mattresses, bedding, stoves, water heaters, kitchen ware, etc. Largest assortments in all lines; lowest prices on all grades of goods; best terms for all classes of buyers.

WONDERFUL NEW PEACH

Wonderful new peach, "Shamrock," that comes in just after Salway, which keeps until February. It is a large yellow peach, highly colored, like Orange Kling, has a rich flavor, bears very heavily on all parts of the tree, and sells during winter at 10c and 15c a pound. Three growers near Los Angeles have had control of this peach the past four years and would not sell any trees, but they have netted $400 to $500 an acre each year. My trees are the first ever offered for sale. Price $25.00 a hundred, or 50c each. Also have Foster, Crawford, Susquehanna and Salway at $10 a hundred. All trees two years old.

O. C. LANE, R. F. D. Box 70, Burbank, California.

suckers which were allowed to grow undisturbed at the base of the tree trunk and was found also upon the crown roots of the tree. The apple trees which were worst infested grew in a citrus orchard near the house. An orange tree and several lemon trees were less than 20 feet from the three infected apple trees, and not a single mealy bug could be found on any of the citrus trees. Fearing that they might take to the citrus trees, the owner of the property promptly grubbed up the apple trees and burned them, thereby eliminating any possible chances of infection. In a number of yards other apple trees were found likewise infested with this insect.

Pear (Pyrus communis). Were as generally infested as were the apple trees in the same manner.

Remedies.

This mealy bug has not been a pest yet in any locality. In case they infested the walnut trees as badly as the citrus mealy bugs infests the citrus trees, it would be almost hopeless to combat it with anything but parasites.

That it has never become a pest during past years is no positive proof that it will not become so in the future, so it is with care that we are keeping watch of this insect.

On deciduous fruit trees some active steps have been taken to destroy all infestations, so I may include in this article the most practical means of extermination or eradication of this pest on such trees. It is a fact that such deciduous, or other fruit trees, as are allowed to grow in the yards, around the houses or barns, and in pastures, are more liable to be infested with injurious insects than trees in a well cared for orchard. If you have such trees it is necessary to either take care of them or to cut them out for your own safety, if you are an orchardist, even though you have a few deciduous trees in a citrus region. If your trees are infested with this mealy bug it may be well to heed these suggestions:

1. Cut down the trees, grub out the roots, and burn all over the hole, if your fruit trees are of secondary value to citrus growing.

2. If trees are valuable keep down all suckers and destroy the Woolly Aphis by spraying with the Carbolic Acid Emulsion. It will also kill the mealy bugs. Pour a weak solution of this emulsion around the crown of the tree at repeated intervals of two weeks.

3. Spray when the tree is dormant, using ten gallons of the emulsion per tree.

4. Be sure that the spray is applied to every crack and crevice at not less than 180 pounds of pressure. Repeat the application three times at intervals of one month.

CALIFORNIA SOIL SURVEY.

During the last fiscal year the Bureau of Soils, United States Department of Agriculture, made soil investigations of about 1,000 square miles in California, bringing the total of the soil survey work in that state to 11,256 square miles, or 7,203,804 acres.

During the winter of 1910-11 a survey will be made of Fresno county, covering an area of 1,000 square miles.

Since the Department of Agriculture began soil investigations in California, in 1901, the following areas have been surveyed: Bakersfield, Colusa, Fresno, Hanford, Imperial, Indio, Los Angeles, Lower Salinas Valley, Modesto-Turlock, Portersville, Redding, Sacramento, San Bernardino, San Gabriel, San Jose, Santa Ana, Stockton, Ventura and Yuma, and the counties of Yolo and Yuba.

PRUNING APPLE TREES.

By J. W. Mills.

After the young apple trees are planted they should be cut to a uniform height of about eighteen inches. Should there already be branches at about that height and the branches are evenly and widely distributed, there is no reason why the proper ones should not be selected and left to form the head of the tree. In selecting these branches, imagine as nearly as possible what their position and appearance will be when the tree is five or ten years old. Never allow branches to develop opposite each other on the main stem. This makes two knots at one point which weakens a tree. If one branch happens to split off, the opposite one is sure to go as soon as a heavy load comes on it.

If the apple tree is only a straight whip when it comes from the nursery, cut it off about eighteen inches high and select three or four (no more) branches located as described above, and rub off all the others which start so as to throw all the growth into the permanent branches. These should never be pinched back in order to make them branch the first year. All young trees should be allowed to make as much growth as possible, and if the branches are nipped, the growth is checked just when it should be most active. Experiment with apricot trees showed that summer pruning retarded the growth more than one-half.

At the time of pruning after the first summer's growth the permanent branches should be cut back to eight or ten inches and all others removed entirely. Trees of a spreading habit usually require pruning to inside buds in order to keep them from spreading too much. The idea is to secure the proper spread and carriage of the head, and pruning to inside buds at one time and outside buds at another, may be necessary. Sometimes an open space in a tree requires pruning to a bud pointing in that direction. Trees of the Northern Spy type usually require continual pruning to outside buds.

At the third and fourth pruning, the branches should be left a couple of feet long, as it is on these that fruit spurs will develop later, and the tree will be old and strong enough to bear. At all of these prunings no more than two branches should be left to each branch of the previous year's growth. Subsequent prunings should be confined to keep the head of the tree properly thinned and stocky. If the tree is properly pruned till it is four years old there will never be any need of taking out large branches, at least not until the tree is so old that it requires severe cutting back in order to rejuvenate it.

The small short branches or twigs that grow on the older wood should never be trimmed or broken off, for they are the fruit spurs.

Pear trees should be pruned in the same way, the idea being to secure a stout well-balanced head that will admit sunlight to properly ripen and color the fruit and at the same time hold up a heavy load.

The chief difference between pruning the apple and pear is that the latter requires to be pruned to spread the top in most cases while most apple trees are of a spreading nature.

There are a few exceptions in certain varieties. Winter Nelis, for instance, should be allowed to have about its own way till it gets over its rampart growth.

Home Grounds Beautiful

THIS MONTH.

This is no exception to every other month in the year in that it is a good time for fertilizing the lawn. If stable manure is used, see that it is thoroughly rotted. Scatter over the surface and wash into the soil with water under force from the hose. After permitting this to cover the entire lawn for a week and watering occasionally, the surface should be raked off. If the manure is well rotted no weed seeds will be carried into the lawn. Fine bone meal is excellent for applying to the lawn, and if stable manure is not available, or if preferred, complete commercial fertilizer may be used. True up the edges, and if there are bare spots or spots foul with weeds, deep raking and reseeding will help. Old lawns, especially where Bermuda is getting a start, are often helped materially by using liberally of sweet clover seed.

Such bulbs as amaryllis vittata, agapanthus, cannas, dahlias, iris, tuberoses, and especially early gladiolus, should be put in the ground. The plantings of gladiolus should be continued practically for months. This beautiful flower is so prolific and so easy of culture, requiring no more care than potatoes, that it is strange it receives no more general planting.

In annuals, pansies, stocks, verbenas and salvia may be lifted from seed beds and put into the open ground. Sweet peas may yet be planted, although they will require more care than those planted earlier. Sow seed of asters, coreopsis, alyssum, poppies, pinks and other hardy annuals. All deciduous ornamentals should be planted at once.

SEQUOIA.

We are constantly seeking the exotic or the artistic from foreign lands. "Imported" gives added value in many minds. The more striking or more valuable plant growing at our own door is ignored, and foreign seed introduced and coddled. The German appreciates the beauty of our wonderful poppy, and hundreds of pounds of seed are sent to that country every year. Few Californians appreciate it sufficiently to aid nature in its production. It's our state flower. Let us make more of it.

Along another line, we note in The Practical Farmer, Joseph Meehan speaks of our Sequoia as the California Big Tree, and recommends its planting in the East. Yet how many California home owners honor their own state—or themselves, rather—by planting this noble tree. The writer has one in his yard, and derives from it much pleasure because of its beauty, more because it's a "California Big Tree."

The Eastern writer says: "Almost everyone has heard of the giant trees of California, the 'big trees,' as they are called, and it has been the privilege of some to have seen them in their wild state. In cultivation there are very few of them to be seen, for the reason that there is a fungus that attacks the foliage, so weakening the trees that they dwindle away and eventually die. Those who do not know that a fungus is working the injury suppose that the tree is too tender for growth among us, but this is far from the truth; the tree is perfectly hardy, at least it is in Eastern Pennsylvania, never having been hurt in even the severest winters. There are very few of them in collections in the East, but it is solely because persons know no better than to believe that it is not a hardy tree. All that is required is to spray the tree with Bordeaux mixture twice a year, spring and autumn, and this would not be a hard matter, now that all good fruit growers do it to their fruit trees at least once a year. This 'big tree' is looked on as one of the wonders of the world, an additional reason for having a growing tree on one's grounds. Experience with the few trees planted about Philadelphia shows that the tree prefers a situation where the ground is rather moist than dry; in fact, one flourishing tree of it here is growing near a running stream from a spring of water."

THE ARCHITECTURE OF FARM HOUSES.

One of the next steps in agriculture should be a revision of farm architecture. Only a small percentage of country residences please a cultured eye or afford sanitary comfort to their occupants. Most of them are devoid of any semblance of art. Outwardly plain and severe, they are inconvenient, insanitary and unattractive within. If farm people spent half as much time in their homes as city folk spend in theirs, rural mortality would be appalling. But farm families as a rule are blessed with vigorous health in spite of poorly ventilated houses. Outdoor activities offset in large measure the effects of unhealthful conditions indoors. A much higher degree of health, however, should obtain in the open country.

Many a farmer buys additional land who could better invest his surplus in a new or remodeled home. Usually where men are unsentimental, autocratic heads of houses there is little of beauty or comfort in their homes. Our best farm dwellings have been built at the instigation of women. Since women spend most of their time in houses they have a right to dictate plans and demand their execution. Farmers' wives are entitled to better homes than the majority of them live in, and their husbands in thousands of cases could well afford to provide them. We would not engender domestic dissention, but we urge farm women to campaign for more attractive, healthful and convenient houses.

New types of farm houses equipped with modern heating and water systems, and expressive of simple architectural beauty, can be constructed at an average expense not in excess of what the bulk of ordinary modern farm houses cost. There is excuse and opportunity for a deal of thinking, studying and planning by those who would build a farm house with a quiet, simple individuality and a maximum of practical conveniences that conduce to mental and physical comfort. It is time that our agricultural colleges considered this problem of farm architecture.—Breeders' Gazette.

Unfruitful orchards, as a rule, are so because the soil is deficient in plant food.

Saucer peach trees of Orange county are in full bloom.

Garden and Field Crops

THIS MONTH.

With the high price of potatoes, doubtless extensive plantings will be made this season, and in the more favored sections the present month is a good time. The heavy rains have fitted the ground, and potatoes planted now will probably have rainfall enough to carry them to maturity without irrigation. For present planting Early Ohios or Early Rose are perhaps the best.

Rhubarb roots may be reset now, as may horseradish, asparagus and onion sets. Sow peas, beets, carrots, cabbage, lettuce, parsnips and radish. Plant onion sets, rhubarb roots, cabbage and cauliflower plants, shives, horseradish, tarragon and asparagus roots. On the hot beds, sow egg plant, tomato and pepper seeds.

Resetting of raspberries, strawberries and all small fruits should be made at once. They are now forming roots for the new season's growth, and the sooner in permanent place the better. Of course, grapes and all deciduous fruit should be planted at once.

Plants susceptible to frost should be prepared for, though they may not be put into the ground until the next month, but spade in thoroughly rotted stable manure.

FARMERS ATTEND AUTOMOBILE SHOW.

Thousands of well-to-do farmers, accompanied by their wives, their sons and daughters, assisted greatly in making the Chicago Automobile Show a big success. They outnumbered the city men almost two to one in their purchases, and practically forced those makers who have appealed to the fads of the city alone to change their policies and begin to think of taking care of the farm owner first.

It was exceedingly noticeable this year that the women were more of a deciding factor in many of the sales than ever before in the history of the motor car. Among the many demands of the farmer and his family, comfort seems to be the most important. Of course, they want a car that is of large enough carrying capacity so that the family uses will add to its service value, and a car that is good to look at, yet the farmer does not at any time lose sight of what he considers to be one of the most important factors—comfort.

Considering the matter from the purchaser's standpoint, appearance attracts his attention first, but when it comes to a demonstration of actual use, comfort is always demanded by the experienced buyer. The question of comfort has many sides, and every point which affects it must be considered. It was once thought that if the springs were properly flexible, comfort would necessarily follow, but it is now just as important that the seats be of proper height and depth, and that there be sufficient room in front between the seats and pedals to avoid a cramped position.

The wheel base should be long, to neutralize the inequalities of the road, and the larger the diameter of the wheels, the less shocks of any kind will be transmitted to the passengers. The position of the steering wheel in relation to the seat is important to the driver, as a cramped position tires.

Another very important thing which is receiving more consideration than ever before is the reliability of the maker. Farmers are now buying motor cars in very much the same way they have for years purchased their live stock. That is, they are exceedingly careful to look into the pedigree, as it were—they know that quality is never cheap, and the motor car with a pedigree and a reliable guarantee from a well-established and reliable maker cannot be produced in a minute, nor sold any cheaper than it cost to produce.

The man from the farm who is buying a car is unconsciously lending his aid and assistance in forcing those who manufacture to give full value, and, as everybody knows, this tends to crowd out of the large industry fictitious values placed on low quality cars, or the so-called wildcat features of the automobile business.

A careful investigation among the various salesmen of the many cars represented at the show indicates the average price paid for all cars to be somewhere around two thousand dollars, which proves that more of the better quality and better than average priced cars are being sold.

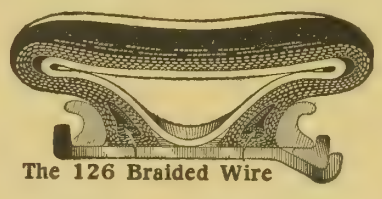
No Rim-Cutting
No Overloaded Tires

In motor cars, one-fourth the tire cost is due to rim-cutting—one-fourth to overloading.

We have perfected a tire which can't be rim-cut—called Goodyear No-Rim-Cut tire. And, to prevent overloading, we are making that tire 10 per cent over the rated size. The use of this tire, with the average car, means to cut tire bills in two.

These patented tires, until lately, cost one-fifth more than other standard tires. Yet last year our tire sales trebled—jumbed to $8,500,000—because these tires save money.

Now they cost the same as standard clincher tires. And 64 leading motor car makers have contracted for Goodyear No-Rim-Cut tires for their 1911 models.



The 126 Braided Wire

The No-Rim Cut Tire

This picture shows a Goodyear No-Rim-Cut tire as it fits any standard rim made for quick-detachable tires.

When you use this tire the removable rim flanges are set to curve outward—as shown in the picture.

The tire comes against the rounded edge, and rim-cutting is made impossible.

We have already sold half a million Goodyear No-Rim Cut tires. We have run them deflated in a hundred tests—as far as 20 miles. In all this experience there has never been a single instance of rim-cutting.

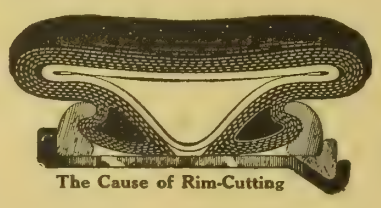
All the worry of rim-cutting—all this ruin of tires—is avoided forever with No-Rim-Cut tires.

Ordinary Clincher Tire

Before the invention of No-Rim-Cut tires the clincher tire was almost universal.

With clincher tires, the removable rim flanges must be set to curve inward—as shown in the picture—to grasp hold of the hook in the tire. That is how the tire is held on.

Note how those thin flanges dig into the tire. That is what causes rim-cutting.



The Cause of Rim-Cutting

In event of a puncture the tire may be ruined beyond repair in a moment. Fully 25 per cent of all tire cost has been due to the ruin of rim-cutting.

We have invented a tire with an unstretchable base. We vulcanize into the base 126 braided piano wires. Nothing can possibly force this tire over the rim flange. But, when you unlock and remove the rim flange, the tire slips off in an instant.

When the tire is inflated the braided wires contract. The tire is then held to the rim by a pressure of 134 pounds to the inch.

That is why the hooks are not needed. Not even tire bolts are needed. The tire base is unstretchable—it can't come off.

This feature we control by patent. It is the only way known to make a practical tire with an unstretchable base. It gives us the only safe hookless tire—the tire that can't be rim-cut.

Tires 10% Oversize

Look again at the pictures. Note how the No-Rim-Cut tire begins to flare right from the base of the rim. It isn't contracted farther up as is the clincher tire.

That fact enables us to make No-Rim-Cut tires 10 per cent wider than rated size and still have them fit the rim. And we do that. We give you this 10 per cent extra tire without any extra cost. That gives you 10 per cent more carrying capacity. It adds 25 per cent to the tire mileage.

That extra size takes care of the extra weight—the top, glass front, gas tank, extra tire, etc.—which most owners add to their cars. It is this overloading which causes blow-outs, and this extra size avoids them.

When you get a Goodyear No-Rim-Cut tire you get rid of rim-cutting entirely. You get a tire 10 per cent oversize. And all without extra cost. These two features together, with the average car, save half on one's tire bills. This is the reason why the tire demand is turning so strongly to Goodyear No-Rim-Cut tires.

Our new Tire Book tells a hundred things you will be glad to know. Ask us to send it to you.

A new development company called the United States Farm Lands Company, claiming a capitalization of thirty million dollars, proposes to be a factor in the development of the Sacramento valley.

County Horticultural Commissioner Hecke, of Yolo county, reports that last season the red spider was especially active in almond and prune orchards and recommends thorough application of sulphur this season.

A bill has been introduced which provides for the formation of "mosquito districts" to be under the control of boards of supervisors of counties which take up the work of prevention of fever and malarial conditions.

Live Stock and Dairy

Dairymen and stockmen are requested to write of their experience. Mrs. Sherman is always willing to answer queries and this, with experience of other workers, will make this department of greater value.

THE COW-TESTING ASSOCIATION.

A New York State Fair Prize Esasy.

The value to a farmer of testing his herd is so great that it seems hardly possible it can be necessary to stir any farming community to a realization of the fact. How can a man determine whether his cows are worth their keep unless he tests? He may know at the end of the year whether he has made or lost money on his herd, but that knowledge is of very little value, for he has no idea which cows helped him make a profit or which occasioned him a loss. The only possible way to know just what each cow is doing in return for the money invested in her and spent on her, is to keep an accurate account of the quantity of milk she gives during the year and of what quality it is, and so learn positively whether she is a source of profit or loss.

To operate a testing machine is very simple, and any careful man can do his own testing; but it certainly is an advantage to have it done through an association of friends and neighbors, for the initial expense of a machine can be divided among several, and a larger machine can be bought; also a certain friendly rivalry will be engendered which acts as a stimulus for every member of the association to do his best, in the desire to beat the others, while seekidg to improve his own herd.

Profitable herds do not "come," they are made, and made only by the most careful attention to details, of which testing is probably the most important. Cows are very deceiving machines. Some will produce a large quantity of milk for a short time, others only a fair quantity for a very considerable period; the milk of some individuals is very rich in butterfat, of others it is very low. Outward appearances are oftentimes misleading and are never to be wholly relied on, and the man who depends on "guessing" as to the comparative production of his cows will usually find, on testing, that his ideas are far from the truth. And yet positive knowledge can be gained by an outlay of very little time or money, and the results are sure to be astonishing in many ways.

It often happens that a farmer feels obliged to reduce his stock for one of various reasons, and unless he has tested and knows, he is quite apt to dispose of better animals than he retains, being totally ignorant of their true capabilities; whereas he might quite easily be perfectly sure he was selling his inferior animals.

It is a great satisfaction and very valuable knowledge to be able to say at the end of the year just what each and every cow has done for her owner. It costs no more to house, milk and care for a good cow than for a poor one, and very little more to feed her; so it is obviously common business sense for a man to seek to know that each cow he houses is a good one and is not robbing him of the time, labor and money spent on her.

What would be thought of a printer who ran ten presses to do only the same amount of work his neighbor was accomplishing with five? How would the profits of the two men compare? Yet farmers are doing this all over the country—that is, keeping ten machines to do the work five ought just as easily to do, if the man behind them were dilligent in testing and did not hesitate to weed out the "drones." It is small wonder that we so frequently hear the remark that "dairying doesn't pay;" but by persistently and carefully testing the herd, dairying can, in a very few years, be made to become a profitable branch of the farming operations.

During the past few years we have seen a wonderful rise in the prices paid for dairy cattle, young and old. The only thing that has made this possible is the fact that authentic records are kept of the performances of either the animal itself or its parents. At a recent cattle sale, 200 animals brought an average price of about $330 each, because authentic records of either pedigree or performance, or both, had been gathered and advertised. Had these 200 animals been without records of any kind, the probability is that the price would have been nearer $30.

What makes it possible for one man to sell a cow for eight thousand dollars and another to be unable to get even eighty dollars for his? Simply the fact that the higher-priced animal, in addition to being well bred, had been tested and was known to have made a tremendous quantity of butterfat, whereas the cheaper animal was an unknown quantity, and whoever bought her had to take chances on feeding and caring for an unprofitable "machine."

In addition to being invaluable as an aid to the building up of a profitable herd of dairy cattle, testing enables a farmer to prevent a dishonest creamery man from cheating him, for he can readily see whether he is being treated fairly or otherwise by comparing the test received from the creamery with his own average test of his herd. It also materially assists him to determine the relative value for milk production, of the various rough fodders, grains, mill by-products, etc., and an intelligent investigator along these lines will be able to produce milk at the lowest possible cost, and consequently make the greatest margin of profit. In fact, it is hardly possible for dairying to be profitably conducted unless the scales and Babcock test are diligently and persistently used. Every argument is in favor of testing, and it follows, as the night the day, that if it is carefully practiced and the results acted upon, a few years will show an increase in milk yields of several thousand pounds per cow, and the dairyman can rest assured that every animal on which he spends his time and money is paying him a fair return.

Whether the testing is done individually or through an association is immateral, so long as it is done; the advantages are incalculable, and every farmer keeping even only a few cows should decide to commence the practice at once, for success cannot come without it.—Frank W. Weedon.

DO HIGH RECORDS TEND TO PRODUCE NON-BREEDERS?

A careful study of the advanced register of Guernsey cattle shows the following facts: There are 1112 advanced registry records reported in the latest volume, and of this number of cows only 55 were reported not in calf at the close of their year's test, or a total of 4.9 per cent. There were 23 cows of all ages that had produced 400 pounds of butter-fat and were not in calf during their test, or a total of 2.06 per cent.

The percentage of cows, of different ages, which were in calf during the test, was as follows:

In the 5-year or above class, 93.3 per cent.

In the 4½ to 5-year class, 95.5 per cent.

In the 4 to 4½-year class, 97.7 per cent.

In the 3½ to 4-year class, 95.6 per cent.

In the 3 to 3½-year class, 94.9 per cent.

In the 2½ to 3-year class, 96.5 per cent.

In the 2 to 2½-year class, 95.4 per cent.

Putting this test on a little more scientific basis, and requiring all cows, reported as being in calf, to be two months in calf during the test, we have a slightly different result; not as large a per cent being two months or over in calf. Many cows with big records have not been bred until the close of their year's work, but it seems reasonable to expect a cow to be at least two months in calf, and it is an uncertain matter to report them safely in calf in less time. I have therefore selected this period on which to base my figures for this article.

The cows of all ages which were two months in calf during the test, produced butter-fat in the following amounts per year:

90.5 per cent produced 400 to 450 lbs.
92.2 per cent produced 450 to 500 lbs.
90.8 per cent produced 500 to 550 lbs.
85.4 per cent produced 550 to 600 lbs.
79 per cent produced 650 lbs. and up.

Taking the above report to be correct, we have the following results: The association reports over 95 per cent of the record cows in calf before the close of the test. Barring out those cows reported in calf, but not found to have been two months in calf, the records show that 90 per cent is a good average. It would seem, then, that records of 400 and 500 pounds of butter-fat can be made, without impairing the cow's capacity as a breeder, with careful feeding and management; but when a cow is forced to 550 and 600 pounds of fat per year, there is great danger of making her a non-breeder. These figures have been worked out with Guernsey cattle; as the Guernsey association is the only one giving the data required for the above information.—Geo. P. Grout, Dairy Division, Minnesota University Farm.

GOOD STOCK.

Ex-Mayor Chas. N. Taylor of Pasadena was a guest at the Geo. A. Smith Fine Stock Farm at Corcoran, Cal., for three days recently inspecting the pure bred registered stock kept on this farm. Mr. Taylor is a Jersey enthusiast and is thoroughly familiar with the Jersey cow and with her work. He selected three extra fine registered Jersey cows for his ranch at Artesia, where he has already established a herd of pure bred registered Jerseys headed by the great bull, St. Lambert of Ramona No. 62633, which is one of the best bulls on the Pacific Coast. The cows selected by Mr. Taylor are now on a year's official authenticated test which is conducted by the University of California, and it is predicted will make over 400 pounds of butter-fat each with the first calf, and at maturity will make cows that will produce between 500 and 600 pounds of butter each per annum. They are descendants of the greatest American and Island strains and are bred especially for great butter production and promise records that will be a credit to his already good herd. Mr. Taylor is making arrangements to place all of his cows on a year's official test, as he realizes that a year's test is the only measure of a cow's real value as a butter producer.

AYRSHIRE BREEDERS ASSOCIATION.

The 36th annual meeting of the Ayrshire Breeders Association was held at Hotel Manhattan, New York, with about seventy-five members and invited guests present.

The election of officers resulted in the choice of Mr. John R. Valentine, Bryn Mawr, Pa., president; Dr. J. A. Ness, Auburn, Maine; George E. Pike, Gouverneur, N. Y.; J. W. Clise, Seattle, Washington; J. W. Ogden, Morristown, N. J., vice presidents; C. M. Winslow, Brandon, Vt., secretary and treasurer; George H. Yeaton, Dover, N. H., auditor; Charles H. Hayes, Portsmouth, N. H., and John W. Oakey, Bryn Mawr, Pa., executive committee for three years.

A banquet was served, after which President Valentine gave a very interesting and instructive talk on Scotland and the Ayrshire cow, illustrated by stereopticon views of the two types of cows found in Scotland, the dairy type with a marked dairy conformation of large udder and long teats, and the vessel type so-called, being the show ring Ayrshires of Scotland, which are kept simply for showing in the ring.

The concensus of opinion at the meeting was that we had the largest and most enthusiastic meeting we had ever had, and that the outlook for the perfect cow was never so hopeful.—C. M. Winslow, Secy.

PURE BRED LIVE STOCK RECORD ASSOCIATION.

One of the most important and far-reaching movements affecting the interests of breeders of pure bred live stock that has been undertaken in many years was inaugurated at Chicago on Jan. 3, 1911, by the organization of a National Association of Record Societies.

The preliminary steps leading to such an organization were taken by the five record organizations located at the Union Stock Yards some time ago. From the call for the meeting of this organization we quote:

"State and federal laws, state fair and other live stock shows, railroad stock, and other similar matters, affect in more or less degree all breeders of pure bred live stock.

"The pure bred live stock record associations, who represent more accurately than any other organizations the sentiment of the breeders of pure bred live stock, should give these matters attention.

"It is needless to add that existing laws, regulations, classifications and rates may be modified and that pro-

BUY THE LOWEST COST ENGINE MADE. Lowest fuel cost; lowest up-keep cost; easiest on the machine it operates, delivering steadier power than any other gasoline engine, adapting it especially for operating farm machinery, with better results and least waste of grain. Lowest fuel cost for it runs on Gasoline, Kerosene, Distillate, Gas or Alcohol and has perfect lubrication. Lowest cost because it delivers greatest available power per horse. A slow speed, high duty engine. Starts easier and quicker than any other engine, occupies less space, is less cumbersome, with less vibration, therefore adapting it for either stationary, portable or traction use. IT IS THE POWER CONTRACTOR'S FAVORITE ENGINE. No engine made has so wide a range of use. YOU WILL MAKE A MISTAKE IF YOU DO NOT WRITE US FOR INFORMATION. 1½ H. P. to 5½ H. P. single cylinder. 6 to 20 H. P. two cylinder. 30 to 50 H. P. four cylinder. State your requirements and get our advise. THE TEMPLE PUMP CO., Manufacturers, 472 West 15th St., Chicago, U. S. A. LLOYD R. TAYLOR, Modesto, Cal.

posed laws, regulations, classifications and rates may be favorably influenced by united action on the part of the record associations, representing the breeders of pure bred live stock.

"The question of organizing a national association whose membership shall be limited to the record associations recording pure bred live stock has been quite fully canvassed during the past season. Sentiment seems to be quite uniformly favorable. The general idea appears to be that such a national organization should include all of the recognized associations that are recording pure bred live stock, that each association should be represented in the membership by the president and secretary of such association; that the directorate of such national organization should consist of one representative from each association; that such directorate should select an executive committee of six, selecting one representative for each of the following live stock interests: Beef cattle, dairy cattle, draft horses, light horses, sheep and swine; that such executive committee should have charge of the work of the national organization and should direct such publicity and other work as in their judgment will be beneficial to the interests concerned."

The associations forming the membership of this national organization represent more than 100,000 active breeders of pure bred live stock scattered in every state in the Union. It is probable that no one industry in the United States has within its active membership a larger number of men of acknowledged influence, integrity and standing than the live stock interests represented in this new national association. They are the breeders, the constructive workers who have built up breeds that are admittedly the equal and in many cases the superior of any breeds in the world, and their views and ideas on matters pertaining to live stock matters must inevitably receive attention and careful consideration.

BLOAT.

A correspondent in Wallace's Farmer gives of his experience in handling bloat from which he never lost an animal. His method is as follows:

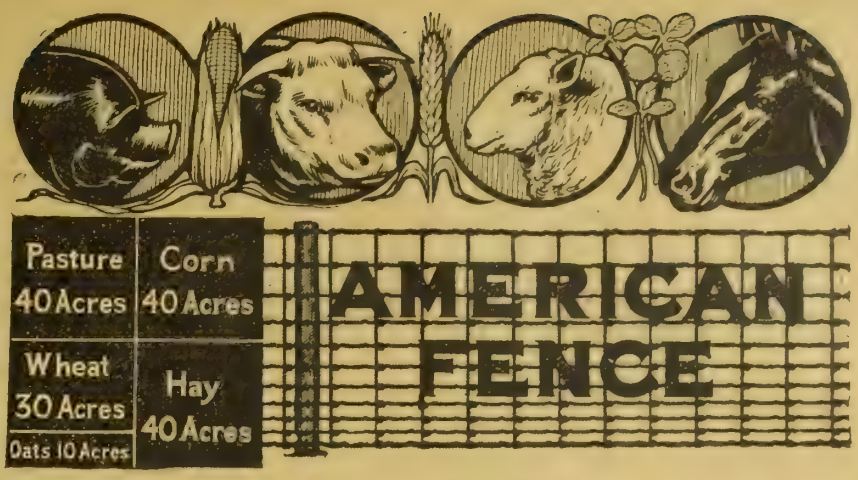
Get a piece of three-ply, three-fourths inch hose, six feet long. If an animal shows signs of bloat, take a common halter and put on the animal, and place a stick about two inches in diameter in the mouth. Then run the hose over the stick and down into the throat until it strikes the gas, which will be carried out by the tube. The trouble will be relieved immediately. The hose provides an outlet for the gas that causes the bloat, and I like this method better than to use the trocar or knife to cut through to the stomach.

SEVEN-DAY BUTTER RECORD.

Pontiac Clothilde de Kelii, a Holstein-Friesian cow, owned by Stevens Brothers, of New York, has broken the world's seven-day butter record, producing 37.28 pounds. Since 1908 the record has been 35.55 pounds, held by Grace Fayne II, Homestead.

If the beginner will start with not more than two or three sows, in pig when purchased, he can acquire much valuable experience with even so small a number, while his risks will not be great. The next year he may add to the number of sows, secure a suitable boar, and by slow but careful increase in the number of sows bred each year, if good management and freedom from disease prevail, should soon find himself with a profitable herd.—Coburn's "Swine in America."

Anthrax Cure, Milk Fever Outfits. See O. J. Weber Co., 225-227-229-231 East Sixth Street, Los Angeles.



Fences cost almost nothing compared with results obtained

A farm of 160 acres fenced into five fields, as shown in the diagram, takes 1,040 rods of fence. At fairly reasonable prices the year's yield from this farm is:

Wheat	$600.00
Oats	157.50
Hogs	400.00
Cattle	1000.00
Market value of year's crop	$2157.50
Cost of complete fence	**$350**

Or, in ten years, value of yield $21,575—and the fence still good

What did the fence do? Besides enclosing the fields it facilitated crop rotations and the feeding of stock. Without the fence the same profit could not have been realized from the stock.

Fences cost almost nothing compared with results obtained.

American fence is made better than ever. It is a thoroughly galvanized square mesh fence of weight, strength and durability. Large wires are used and the whole fabric is woven together with the American hinged joint (patented)—the most substantial and flexible union possible. Both wires are positively locked and firmly held against side slip and yet are free to act like a hinge in yielding to pressure, returning quickly to place without bending or injuring the metal.

Dealers Everywhere Stocks of American Fence are carried in every place where farm supplies are sold. The Fence is shipped to these points in carload lots, thereby securing the cheapest transportation, and the saving in freight thus made enables it to be sold at the lowest prices. Look for the American Fence dealer and get the substantial advantages he is enabled to offer. He is there to serve the purchaser in person, offer the variety of selection and save the buyer money in many ways.

CONTENTS THIS WEEK

EUCALYPTUS GLOBULUS.—Cover.

PEST OF DECIDUOUS TREES.—163, 164.

FACTS REGARDING THE LEMON.—163, 167.

CITRUS AND TROPICAL FRUITS.—Cloverdale Premiums; Nitrate of Soda; World Wide Tourist; Whitefly Fungus in India; Lime in Orange Orchard; Fertilizer for walnuts, 164, 165, 166.

DECIDUOUS FRUITS.—Pruning Apple Trees; California Soil Survey; 167, 168.

HOME GROUNDS BEAUTIFUL; This Month; Sequoia; Archectecture of Farm Houses; 169.

GARDEN AND FIELD CROPS.—This Month; Farmers Attend Automobile Show; 170.

LIVE STOCK AND DAIRY.—Cow Testing Association; High Records Produce Non-Breeders; Good Stock; Ayrshire Breeders Association; Pure-Bred Live Stock Record Association; Bloat; Seven Day Butter Record; 171, 172, 173.

EDITORIAL.—Use More Care; Notify Your Friends; Not so Slow a Crop; Twenty-first Annual Convention State Bee-Keepers; Aid to Agriculture, 174.

AGRICULTURAL NEWS NOTES OF THE PACIFIC COAST.—Northern, Central, Southern, The Coast, 175.

PRACTICAL POULTRY CULTURE.—Prevention of Diseases; New Zealand Hares; About Ducks; The Package Sells the Goods; 176, 177, 178.

TIMELY RANCH SUGGESTIONS.—Sugar Consumption in the United States; Some Popular Proverbs; Postal Deficit, 180.

QUESTIONS AND ANSWERS.—Best Dairy Breed; Onions; Oranges without Irrigation; Bermuda; Pruning Grapes; Mange; Warbles; ;Planting Near Pepper Trees; Indian Runner Ducks; Rabbit Troubles; Casabas Splitting; Apple Seed; Grafting Almonds; Curing Olives; 181, 182.

VETERINARY.—Bloating in Cows; Summer Itch; Worms in Dog; 183.

IRRIGATION AND FORESTRY.—For Settlement; Blowing of Sandy Soil, Horse Power; Fertilizers True to Analysis; 184, 185.

GENERAL HOUSEHOLD NOTES.— Get to Work; Haughty Maude Sutton; A Good Consomme, 188, 189.

PRODUCE MARKET.—Los Angeles Market, San Francisco Market; Deciduous Market; Citrus Market; 190, 191.

USE MORE CARE.

Mr. Powell's connection with the Citrus Protective League is beginning to make itself felt, and in his characteristic way the new manager is taking the public into his confidence and asking for co-operation. This is the plan which succeeded so magnificently in the orange and lemon decay investigations, and we believe it will also with the larger questions with which Mr. Powell will have to do in his new position. The article in last week's Cultivator containing a statement of the accomplishment and hopes of the league gives an outline of some of Mr. Powell's work. This week the statement given by him to Senator Flint is given place on the first page because of the vast fund of information of value to citrus people.

A circular has been issued calling attention to the decay of citrus fruits in transit. This is along the line of Mr. Powell's efforts while in the Bureau of Plant Industry, and is merely a reminder of facts which every fruit packer and picker knows, but this reminder should prove of especial value at this time, because, as stated in the circular, after the first of February decay of citrus fruit while in transit is likely to increase. Everyone working in the orchards, and especially pickers, should observe the greatest possible care. A sound orange with uninjured skin does not decay. If the fruit handlers will keep this fact before them constantly, sound oranges will be delivered to the packing houses, and the methods employed there should send the fruit sound into the Eastern markets.

NOTIFY YOUR FRIENDS.

Mr. T. A. Graham, assistant general passenger agent of the Southern Pacific, informs us that the colonist rate will be effective March 10 and continue until April 10. The rate will be $25 from the Missouri river, $32 from St. Louis, $33 from Chicago, and proportionately low from other points. Mr. Graham says that indications point to much travel to California during this short period. The need for more labor in California orchards and vineyards should inspire many people to write to their friends in the East regarding these advantageous rates.

The Cultivator's ability to help its friends has been tested almost to the limit lately in the great number of letters which have come requesting personal mail answer. So far we have tried to comply, but we remind our readers that it makes a very heavy burden on the editorial force. We would urge subscribers to use the query columns as much as possible, for in supplying information through them we not only benefit the inquirer but many others who have similar questions in mind. Of course, in emergencies where stamp is enclosed we will answer if possible, but we must renew our suggestion made many times, that to give intelligent answer we must have more information than comes with some letters. Especially is this the case with veterinary queries. Mail answers from attorney or veterinarian can only be given when fee accompanies letter. One subscriber asks what makes his horse lame. There are a thousand complications which may enter into a horse's lameness and only personal examination can develop the cause, so that such a question affords no opportunity for an intelligible answer. Many other queries are so stated as to draw out a fund of very valuable information.

NOT SO SLOW A CROP.

Many of our Californians who were born in the Eastern states cannot overcome the idea that forest tree planting is only to be undertaken by the young, or, when planted by the older ones, will benefit only succeeding generations. Even where we have watched the rapid development of the "miracle tree," as the eucalyptus is sometimes called, it still seems that the planting of a eucalyptus seed means years of waiting. While this is true in a sense, yet the benefits to the community in general are such that tree planting should be encouraged where conditions are right. Probably three-fourths of the trees now of any size in this state were planted more as windbreaks, as ornamentals, or for shade, than for timber purposes. Many plantings have been made for fuel, but the worth of eucalyptus as a valuable hardwood has been proven, and we believe wider planting will obtain from this time on. This is not meant for an encouragement of the wild promotion schemes which have held out inducements of fabulous profits. Fortunately, these concerns are not finding the green pastures which they did two years ago.

Specializing and standardizing seem to have won the day and nearly every paper circulating in fruit-growing sections is urging more particular attention to special crops and to growing and offering only the very best. This has long been the California way, but it is worthy of more intense application. The 3000 mile trip to market should be encouraged by offering such fruit to Eastern buyers as they can never produce in their climate. Let us make the most of our climatic and soil conditions. The best fruit is none too good.

California beekeepers are elated over recent rains. The feeling was expressed prior to the rain that the long drouth might have affected the growth of the native honey plants to such an extent that even abundance of later rains would not bring out the best of bloom, but this rain has been so copious and the sage and other honey plants seem to be responding so quickly that the prediction is now freely made that with fair conditions continuing to the end of the season a big flow will result.

The Cultivator has received many valuable suggestions from subscribers writing of their experience, and again by sending in clippings from some paper which has proven of help to them. This spirit has increased and recently the number of such suggestions has also increased. We mention this in the hope that others may wish to pass along the good things which have been helpful to them in their ranch work. The Cultivator affords a good medium for the exchange of ideas and is more than willing to be helpful.

San Diego is busy sawing wood in its exposition work. The proposition is to make the entire architectural plan the creation of a "mission city." Frank P. Allen, architect of the Alaska-Yukon Exposition, and Bertram G. Goodhue, noted New York architects, have been put in charge, and John C. Olmstead, landscape architect, has in hand the landscape work.

The first butter scoring contest of the season at the University Farm closed on entries last Monday.

TWENTY-FIRST ANNUAL CONVENTION CALIFORNIA STATE BEE-KEEPERS ASSOCIATION.

The twenty-first annual convention of the California State Beekeepers Association will be held in the Chamber of Commerce assembly rooms in Los Angeles, February 27th to March 1st. The first session is on Monday evening, the 27th, which will be called to order by President B. J. Burdick of Redlands. An address of welcome will be made and responded to by Mr. Mendleson of Ventura county. Mr. E. B. Shaffner of Los Angeles will sing. A reception and social time will then occupy the remainder of the evening. The next morning, February 28th, the convention will get down to work with reading of minutes of last meeting by Secretary A. B. Shaffner, reports of committees and other business. At ten o'clock the program proper will begin.

Tuesday Morning.

Establishing an apiary where there are no conveniences, L. L. Andrews, Corona; Keeping Bees in Pioneer Days, Delos Wood, Santa Barbara; Requeening an Apiary, Albert Dodge, Pasadena; Shade in Apiary, John G. Carey, Santa Paula; Queens, C. A. Worth, Washington; Building up Bees for Honey Flow, J. W. Kalfus, San Jose.

Tuesday Afternoon.

Non-swarming, S. L. Griggsby; Black Brood, Louis Sinn, Reedley; Deputy Inspectors, Chas. C. Schubert, Santa Monica; The Way I Find Things in San Diego County, Z. Quinsey, Ramona; Apiculture in Santa Barbara County, Fred A. Parker, Lompoc; Report of Committees and Question Box.

Tuesday Evening.

How I Make a Crop of Extracted Honey, J. W. George, Imperial; Comb Honey, H. F. Mellen, Acton; Black Brood, Foul Brood, Laboratory Experiments, Prof. Ralph Benton, Los Angeles State Normal School; Report of Committees on Better Organization.

Wednesday Morning.

Fluctuations of Market, W. R. Wiggins, Los Angeles; Unripe Honey on the Market, G. J. Lynn, Los Angeles; A Retail Honey Trade, A. Seligman, Los Angeles; Co-operative Marketing, J. B. Neff, Conductor of Farmers Institutes for Southern California; Report of By-Laws Committee.

Wednesday Afternoon.

Election of Officers; How a Man with Small Means May Go Into the Bee Business, W. H. Allen, Santa Paula.

A. Ramble, T. O. Andrews, Corona; "Looking at You," C. B. Messenger of the California Cultivator; Selected, M. H. Mendleson, Ventura; My Experience, C. R. Chadwick; Flora of California, E. D. Bullock; Honey as Bank Security, First National Bank of Los Angeles; Importance of a Home Paper, J. W. Ferree, Newhall.

AID TO AGRICULTURE.

Some classes have complained because of the great appropriations made in aid of agriculture by nation and state. Of course, there is no other industry which calls for such liberal appropriations. This is not because of charitable consideration of the farmer; in fact, the individual is little thought of in the granting of this appropriation, but it is fully appreciated that not only the direct subsistence of all the people, but of all manufacturing interests is founded on agriculture. This foundation of the welfare of all the people must be cared for. No better investment of state or national funds can be made. It must be admitted that some of the expenditures of committees and commissions are not the wisest. With the vast sums expended other results could not be expected, but on the whole the tendency is good and our prosperity depends upon this policy of encouragement.

Agricultural News Notes of the Pacific Coast

Northern California

Almond growers of Butte county will plant 60,000 almond trees this spring.

The most important deciduous orchard tree in Yolo county is the almond.

Planting of apple trees in Mendocino county this year will be larger than ever.

Over 50,000 young fruit trees have been planted at Placerville, Eldorado county, this season.

Strawberry growers at Florin, Sacramento county, shipped last year $49,580 worth of strawberries.

The state horticultural commissioner has issued a circular describing the potato eel and manner of combating it.

Cotton growers in the Imperial Valley have investigated probabilities of cotton culture at Oroville, Butte county.

The Sacramento Valley Farm Company, capitalized at $125,000,000, has filed articles of incorporation at Oroville.

The snow in the Sierra has reached the depth of four feet and in some sections buildings have collapsed under its weight.

The Western Pacific railroad is contemplating a branch which will reach some of the richest timber sections of the state.

A large tract is being subdivided near Willows, Glenn county, and pumping plants have been installed for irrigation. It is known as the La Croix tract.

Haywards has developed the asparagus industry so that shipments have been made during the past month to San Francisco and at prices most satisfactory.

There are 16,781 head of cows in Humboldt county. During 1910 the county produced 4,273,694 pounds of butter, or an average of over 250 pounds per cow.

During the past year there was sold from the national forests of California timber to the amount of 64,492,000 feet board measure. The stumpage price was $2.36 per thousand feet.

Oroville orange growers are contemplating a combined citrus and snow carnival, the snow feature to be at Portola. The connection between the two towns is by way of Western Pacific.

The contract between the reclamation service and the Truckee Electric Company which provides for diversion of the waters of Lake Tahoe, causes much concern on the part of California irrigators.

The state normal school at Chico, Butte county, has just installed a course in agriculture including study of fruit trees, diseases, spraying, methods of cultivation, marketing, etc. Plots of land will be given for experiments.

Humboldt county creameries report prices on last deliveries as follows: Pioneer Creamery, 39½ cents; Central Creamery Co., 38½; Capital Creamery, 39; Grizzly Bluff Creamery, 38¾; Libby, McNiel & Libby, (condensary) 39¾; Sunset Creamery, 34; United Creameries in Arcata, 39.

Central California

Salinas Valley fruit growers declare that section ideal for the culture of Smyrna figs.

A large number of eucalyptus trees are being planted at Prunedale, Monterey county.

Rain damaged raisins are given as the cause of disastrous prices earlier in the season.

Some potato dealers are caught short and are now paying $1.75 for goods for which they will receive only $1.30.

Many sections of the San Joaquin Valley are favoring the fair grounds bill which provides for state support of county fairs.

The raisin market is still strengthening and while some packers are only paying 3¼, 3½ is readily commanded for fair stock.

The horticultural commissioner of Madera county reports that the warm season necessitates immediate planting of deciduous trees.

The determination to push water transportation up as far as possible in the San Joaquin Valley is being strengthened every day.

Japs are working another corner on us and it is now predicted that onions will reach $5.00 a sack before the new crop comes in.

Stockton shippers are jubilant over the fact that a line of ships operating from the Atlantic to the Pacific will make the Gate City a terminus.

The Kings county fair association recently elected directors as follows: M. Bassett, C. L. Newport, H. R. Cousins, W. H. Brailsford, E. G. Sellers, Geo. A. Smith and Walter Gallup.

Potato growers over the state who are cornering the supply, maintain that no trust has been formed and that the natural shortage only is responsible for the big jump in prices.

The big mass meeting held at Lindsay, Tulare county, last week, endorsed the work of Horticultural Commissioner Schulz, and asked the board of supervisors to sustain him in his work.

Horticultural Commisioner Sharp of Kings county says this is the time to spray for brown apricot scale and recommends distillate oil 28 degrees test, 6 gallons; lye 2½ pounds, water 100 gallons.

Tulare Grange held its annual meeting last week and elected W. A. Bates, master, and Lizzie Patterson, secretary. Resolutions were passed endorsing the mutual fire insurance bill now before the state legislature.

War is being declared on the large gun clubs which have corralled practically all the duck hunting grounds of the state and it is predicted that measures will be started to compel a closed season the year round.

Commissioner Schulz of Tulare county reports the inspection of 536,070 grape vines, 266,700 citrus trees, almost a million small nursery stock, 218,000 deciduous and nut trees, and 30,000 olive trees during the last year.

The new irrigation district on the west side of the San Joaquin Valley is to be approximately 50 miles wide and 25 miles long. The board of engineers recently made extended report to meeting of property owners at Merced.

Southern California

Escondido now has three large fruit packing houses.

Orange county has 45 farms engaged in the production of garden seed.

A thousand acres of cotton will be planted in the Palo Verde Valley this spring.

About 800 cars of oranges are going forward weekly from Southern California points.

A Pomona woman has a $7.50 gold nugget which she claims she secured in the gizzard of a hen she dressed.

Lake Hemet is rapidly filling with the storm waters which have been flowing in since the beginning of the rain.

Hemet is shipping oranges to London by the way of New York. Each box is reinforced with several strands of wire.

Beaumont, San Bernardino county, apple growers have been so successful that this year's planting will exceed all former years.

The rainfall in various parts of Southern California aggregates from seven to twelve inches and is now up to the average.

Mecca promises to plant 6000 acres of cotton. Plantings during the past season netted to the growers from $30 to $60 per acre.

El Centro leads all Imperial Valley points with production of 1700 bales of cotton. Picking is practically at an end for this season.

F. B. Van Fleet has been elected president, and Benton Ballou, secretary of the California Vineyard Improvement Company at Cucamonga.

The forestry department has in the past depended largely upon pines and other native trees in reforesting work, but this season will plant extensively of eucalyptus in Santa Ana canyon.

Plans for the erection of a new sugar plant on the San Joaquin ranch near Santa Ana, Orange county, are assuming definite shape. Capacity will be 600 tons daily.

The main irrigation canal for the Palo Verde Valley is being extended along its western border at the rate of about one mile per week. This will bring a large number of acres under intensive culture.

Imperial Valley irrigators are somewhat concerned over the situation in which they are placed by the insurrection across the Mexican line. The lawless element on that side has it in its power to entirely destroy the Imperial irrigation system.

February 1st divides the rainfall season at Riverside nearly in the middle, that is, its average for a period of 21 years shows that prior to February 1st the fall is 5.38 inches; after that date 5.44 inches. This year's precipitation before February 1st was six inches.

Four large creameries of the Imperial Valley have merged their interests. The new concern will be known as the Imperial Valley Creamery Company with headquarters at El Centro. The combined plant will be located in the immense cold storage plant recently erected by W. F. Holt. The output will be about 210,000 pounds of butter a month.

The Coast

The annual poultry show at Walla Walla exhibited 1500 entries.

Chelan, Washington, reports the production of $73,000 worth of high-grade fruit in 1910.

Plans are being made for an agricultural fair to be held at Zamboanga, Mindanao, P. I.

A campaign is on urging the culture of flax for its fiber in the vicinity of Salem, Oregon.

"No winter killing" is the report of wheat growers in the Inland Empire of Eastern Washington.

The legislature of Oregon is being asked to enact a law to compel tuberculin testing of all dairy cows.

The timber wolves are so numerous in Lewis and Clark counties, Montana, that cattle are being killed by them.

Jack rabbits have become a pest at Forest Grove, Oregon, and roundups and drives are of almost weekly occurrence.

The Whatcomb county Pomona Grange meeting at Bellingham, Wash., passed resolutions favoring direct legislation.

A large number of Norwegian farmers will emigrate from La Crosse, Washington, to Edmonton, Alberta, this spring.

The management of the Portland Fair and Live Stock Exposition is already planning for a big exhibition to open on Labor Day, September 4th.

The Willamette Valley Irrigated Farms Company has acquired 4000 acres of land in Marion county which will be irrigated with waters from the North Santiam river.

The annual meeting of the Albany Creamery Association at Albany, Oregon, showed a total business for its first year of $75,994.30. The amount of butter made was 228,355 pounds. The average price was 35¼ cents.

The recent meeting of the State Horticultural Society at Boise, Idaho, passed resolution calling for laws protecting fruit tree buyers, which brought out strongest opposition on the part of nurserymen present.

The apple orchards in the Inland Empire were threatened with injury because of the warm open season, but the recent cold spell came in time to retard growth and put trees in best of condition for blooming season.

The State Dairy Association of Idaho meeting recently at Twin Falls, was addressed by speakers from the State University. The silver cup offered for the best ten pounds of butter was won by the Jensen Creamery Company of Pocatello.

Fruit growers organizations near Walla Walla, Washington, including Milton, Freewater, Dayton, Waitesburg, Pomeroy, Touchet, Burbank, Wallula and Preston, have combined in a marketing organization. J. B. Taggart of Waitesburg is the manager.

A convention of delegates representing fruit unions of Washington and Oregon, meeting at Portland on January 26th, was unable to reach agreement in the matter of overproduction of apples which many fear in the near future. An adjournment was had until February 28th when the same delegates will meet at Walla Walla, Wash.

1911 SEED CATALOG

If your name is not on our list, please send us your address for a copy. It is a good one, well worth having; sent free and postpaid. We have secured the California agency of the

Prairie State Incubators

The best—bar none. First carload selling fast. Come in and see them—or send for Prairie State Catalog. We also have a carload of the

Baby Buckeyes
50-Egg Incubator for $7.00

Purchaser can operate it for forty days, and if it does not meet with his entire approval, it may be returned to us and the price paid will be promptly refunded. They go like hot cakes. If you cannot come in, send for a Buckeye Catalog. When the chicks are hatched, don't forget the old reliable

West Coast Chick Feed

Nothing better for the little ones

WEST COAST SEED HOUSE

TOMPKINS & CO., Proprietors

111, 113, 115 WINSTON ST., between 4th and 5th near Main. LOS ANGELES

EVERYTHING FOR POULTRY AND THE GARDEN.

The Largest Chick Book Ever Printed---IT'S FREE

The New 1911 64-Page Book of the Pioneer Hatchery Co., the largest dealers in Baby Chicks and Thoroughbred Poultry in the world. Ready for mailing this week. Contains descriptions and illustrations of every kind of chicken, duck, turkey and goose, etc. that we sell. We want to mail a copy to every poultryman in California. We have thousands of books ready. Send your name and names of your friends that are interested today.

We can supply Barred Rocks, Reds, Orpingtons, White Rocks, White and Brown Leghorns, and other kinds of chicks every week at present. Write today.

The Pioneer Hatchery Co.

108-118 East Eighth St. Los Angeles, Cal.

White Leghorns

A Standard Strain of Great Layers and Great Winners. None superior. Prices reasonable. Descriptive booklet of our stock and farm and recipe for mixing best and cheapest egg-producing mash, sent free for stamp. Eggs, stock and baby chicks for sale. Also a grand lot of cockerels.

On a separate farm, we have an extra fine lot of Buff Orpingtons, from which we can furnish stock, eggs and baby chicks at popular prices.

MODEL POULTRY FARM Irvington, Alameda County, California

"Chicks well hatched are half raised"

CHICKS

Strong, healthy chicks that are well hatched.

PRICE PER HUNDRED:

	February	March and After.
S. C. White Leghorns	$12.00 and 10.50	$10.50 and 8.50
Brown Leghorns	12.00	10.50
R. I. Reds	15.00	14.00
Black Minorcas	14.00	12.50

In quantities of 300 and over, 50 cents per hundred less.

San Jose Hatchery

Practical Poultry Culture

THE PREVENTION OF DISEASES IN THE POULTRY YARD.

By Mrs. A. Basley.

It is some time since I have talked to my many friends among the readers of the Cultivator but as I have been asked to contribute an article on the prevention of disease in the poultry yard for this number, I take up my pen again, only wishing that a pleasanter subject had been allotted to me.

Prevention.

"Prevention is better than cure" is an old proverb with a good deal of truth in it. An illustration of this may be observed in the Panama canal zone. That territory was known as the zone of death, thousands perishing there, "dying like flies," the French termed it. But Americans took hold, went to the root of the matter, established proper sanitation and the latest reports from Panama show that the death rate there is lower per thousand than in the city of New York. Prevention has there proved better than cure.

There is no need for chickens in this lovely climate to have diseases, and I am glad to say that progressive poultry breeders in California and throughout the states west of the Rockies are realizing this more and more every year and soon we shall be as successful as the authorities in Panama in preventing disease and California will be acclaimed as the state where are raised the best chickens and ducks, turkeys, geese and pheasants in the whole of the Union. We are rapidly "getting there."

Vigor.

How to prevent disease? The reply to that is "get vigor." Before we decide how to get vigor let us consider what are the diseases that we wish to prevent. What causes disease? Chicken diseases found in this lovely climate are either from germs or from parasites, somewhat similar to the diseases in Panama among human beings. A vigorous, healthy fowl will resist most of the germ diseases unless inoculated, but a weak hen or a puny chick will easily fall a victim.

Contagion.

The germ diseases are principally roup, chicken-pox and tuberculosis. All of these are easily preventable by vigor.

The parasitical diseases are, with the exception of Entero-Hepatitis or blackhead of turkeys, either parasites that are on the exterior of the fowls, such as lice, mites, fleas, ticks, bugs and mosquitoes, or the interior parasites as worms, or mites of several kinds, which can easily be combated by following a few simple rules in sanitation.

I do not hesitate to say after many years of experience, that chicken diseases can all be prevented, and that most of them result from the carelessness or ignorance of the owners of the fowls.

To Secure Vigor.

How do you get vigor in your chickens? First get vigor yourself. The chicken business is not a lazy man's work, as any of the successful poultrymen will tell you. Then follow in your care of the fowls my old "Rule of three," as my friends call it. "Comfort—Exercise—Proper food." These are the three essentials in producing vigor, and vigor will prevent disease. Vigor will produce eggs that will hatch sturdy chicks that will vigorously break open the shell and kick out. Vigor will make them grow quickly, feather well, commence to lay early and be a joy, delight and profit to their owner.

Vigor! Vigor! Vigor! is what we want. Let us review a little the three essentials for vigor. First "Comfort." Comfort means cleanliness, freedom from vermin, sanitary coops, with no drafts but perfect ventilation, shade as well as sunshine in the yards, and a good dust bath to wallow in. Freedom from vermin means a vigorous and observant owner. Let me tell you that seventy-five per cent of the chickens that die of disease are killed by vermin. I will mention a few of these.

Yesterday I received a letter from a man saying, "I have some young chickens whose feathers are all ruffled up, and the chickens themselves are very weak. They have countless very small bugs all over them. These bugs are so very small that it is nearly impossible to see them. They are of a lightish color, and literally swarm all over the chickens. What kind of bugs are they? Where do they come from? Are they the cause of the chickens being weak? What can I do to kill them at once?"

Mites killed his chickens. Mites kill many a sitting hen, and they so weaken others that they cannot hatch out healthy chicks. Mites are the most pernicious and deadly of the pests here. They not only cause intolerable itching, but they puncture the skin and suck the blood of their victims till the chickens, exhausted from misery and loss of blood die. One man told me that one day he found one mite, he did not think much about it, but in three days there were three million of them and he had a big fight on his hands.

Lice are not quite so bad, but they injure the feathers, annoy the hens, prevent their laying and carry disease from hen to hen.

Fleas are almost as deadly as the mites, but are more visible and not so common as the mites. However, one man came to me on a fine September day, with the plaint that he had had seven hundred fine Cornish Indian chicks and the fleas had killed five hundred of them.

Ticks are as hard as anything to fight, but they can can be killed as bed bugs can in Kansas. To get vigor and to keep it you must get rid of and keep clear of all vermin.

Drafts.

Another item that comes under the head of "Comfort" is freedom from drafts. Human beings in California are very susceptible to drafts, especially near the coast. We simply cannot sit or sleep in the house in a draft without getting neuralgia or faceache, earache and a swelled face. It has the same effect on hens; influenza, swelled head and roup most always commence from a draft, often combined with lice.

Comfort also means pure, fresh air, a clean roosting house and clean nests, besides shade in the yards as well as sunshine. A good place to wallow in, with freshly turned up earth, is a great invigorator and keeps the hens clean and healthy. It is their way of taking a bath, and it is absolutely

cruel not to provide the earth bath for them.

The second essential in our "rule of three" is exercise. You know in the human family exercise is needed to keep the digestive and other organs healthy and active. You know how necessary exercise is to athletes, how they are forced to take even violent exercise to keep in training, and when one of them fails in some achievement it is credited to lack of training, lack of the necessary exercise. So with fowls. They must have exercise to give them vigor to keep them vigorous. The utility breeds are especially susceptible to the need of exercise. They are bred for a double purpose, first to lay plentifully and secondly to be good table fowls. These are easily turned into table birds before we want it, instead of laying they get fat, and all for lack of exercise.

Exercise makes vigor but fowls are like a good many human beings; they will not take the necessary exercise unless they are encouraged to do so or made to do so. The usual program is to give them a nice warm mash in the morning, when the sensible things will lie down or go on the perch and take a rest. Why should they exercise? I have seen them so lazy they would not even take the trouble to dust themselves, but lie around until their owner brought them another meal. Did it ever occur to you that the Israelites had to get up before sunrise and hustle to pick up the manna before their wives could bake the cakes or biscuits for breakfast. Work out of doors in the morning is invigorating and chickens should be encouraged to work early. The work of scratching is the proper exercise for hens. It invigorates the digestion, and above all things it develops the egg organs. An egg from a vigorous, healthy hen will hatch into a vigorous chicken and if that chicken is encouraged to scratch, (I do not like to say forced to scratch), from its babyhood, its little ovaries will increase in size, will develop, and the chicken will prove to be as vigorous and sturdy as its mother and most probably a better layer than she. Do not think hens will scratch without some reward to them; they are not such fools as that. If their food is put down where they can get it without work, of course, they will pick it up, and will not trouble to scratch or exert themselves in any way. Fowls in confinement must have encouragement to exercise and the best way is to provide them with a deep scratching pen and scatter all the grain in that, buried under clean straw. By this means you will have vigorous fowls if you feed them the proper food.

This brings us to the third essential for vigor—the proper food. You can do anything you like by feeding the proper ration. The subject is so big, so long, that I think we had better reserve it for another day.

NEW ZEALAND HARES.

The New Zealand hare, recently imported to this state from New Zealand, is pre-eminently the animal for the fancier, as well as for the practical market breeder. Its value as an economic factor in the pressing problem of the world's food supply has been demonstrated and insures the permanence of the industry. His value to the fancier is apparent when one becomes acquainted with his beauty.

His color is a sort of reddish buff,

This open front door makes perfect ventilation

Mandy Lee is Miles Ahead

It is the only Incubator without a "Sealed," Air-tight Egg Chamber. It supplies the life-giving oxygen freely, draws off the carbonic acid gas, and is saving the lives of millions of chicks.

READ the story of the Mandy Lee triumph in our new catalog. Other incubators are already preparing to imitate and profit by our great discovery.

No guessing with a Mandy Lee

You cannot afford to buy an old-theory incubator which may go out of date and be discarded next year. You should know the truth *now* about the great discovery. The book is free. Ask for it.

There IS Something New in Incubators

We have taken the boldest and most important step ever taken in incubator building. See the openings into the egg chamber? They mean the saving of chicks' lives. It is the key to *right* hatching. Ventilation in the Mandy Lee is now perfect. It goes on all the time, neither above nor below, but right *at the eggs*. Every minute of the hatch the life-giving oxygen is freely passing in to the eggs and the carbonic-acid gas is passing out. And correct ventilation is just one of the great Mandy Lee features.

We Don't Guess—We Measure

The Mandy Lee is as far in advance of other incubators in heat and moisture as it is in ventilation. We do not guess at anything. The sensitive regulator controls heat to the fraction of a degree and *we measure moisture* just as accurately with the Mandy Lee Hygrometer (one sent with every incubator). You know what you are doing. *You* measure and control moisture; *you* control the hatch. The Mandy Lee is the all-season, all climate, all condition hatcher, always producing the most and the strongest chicks.

NEW OUTDOOR BROODER
Heated—Storm-proof

Mandy Lee Brooders give direct contact heat to the backs of the chicks. That is *real* mothering, the most important thing in poultry. Hovers are raised and lowered as weather gets warmer or cooler—heated from end to end. Chicks do not pile up and smother. Write to-day for catalog and full information.

Incubators and Brooders

The evidence is conclusive that the PETALUMA is the best Incubator buy that can be made. The best value for the money ever offered and is appreciated most by those who have had varied experiences with other incubators. Why? Because it hatches such large, strong vigorous chicks. More Petaluma Incubators were installed in the large hatcheries last year than all other makes combined. No other incubator in the world has a hatching record to equal the Petaluma.

Write for our Free Catalogue. It is interesting.

We pay freight.

and for fancy they show to far better advantage than the Belgians do. They will mature in less time, and in weight and breeding qualities are the equal of the Belgians.

The meat is white like the breast of a chicken, and there is practically no waste, if they are properly dressed. They lack the heavy oily substances found in ducks and chickens.

For digestibility and nutritive value there is no meat comparable with that of the domestic rabbit. Beef gives 55 per cent of net nutriment; chicken 50 per cent, while rabbit meat yields 83 per cent of digestible nutriment, and is far superior to any other meat.

Not half the meat side of the hare industry has been told. Nor can it be at present.—D. Caldwell, Los Angeles.

ABOUT DUCKS.

By B. A. R. Stocker.

Queries and replies in The Cultivator are often very suggestive. When they talk ducks I feel like chipping in. It is asked, for instance, which will lay most eggs, ducks or hens? Proud I'd be if I could get a band of hens to lay half as much as my Indian Runner ducks.

The work with ducks is heavier because of cooking and mixing mashes and carrying water, but it is simpler. That is, it is possible to learn to do it right and results are sure. Hens I have kept off and on for some thirty years, always a student of books and papers, and to this day I can see no certain sequence between the things I do and the things they do or fail to do. Ducks I have kept perhaps a quarter of the time, have none now, alas! because no market here. Of that more anon. But I learned exactly what they needed, and they everlastingly rolled out the eggs. People ask when do your ducks begin to lay? meaning, October, March? I have but one answer. They begin to lay at four and a half months old, whenever that strikes them, and lay till they die. You don't have to renew your ducks every year like the hens, for they will keep in profit six or eight years.

Far away the best base for their mash I found to be beans, bean screenings, pretty clean and sound, any variety, boiled. Into this we stir bran, middlings, cornmeal, ground beef scraps, etc., in much the same proportions as we use for hens, to make a crumbly mash, only with never a fear of getting a duck too fat. Succulent green feed, as rape, kale, green oats, etc., passed through the cutter goes in the mash. This is important. They won't eat enough of the green to produce the most eggs unless it is mixed in their mash. The mash is fed morning and evening, all they will eat up clean. At noon they have a handful each of oats or other grain in a trough of water. Soft oyster shells at hand.

A pair of Indian Runners ten or twelve weeks old roasted are something superb.

But the market is the big half. Round the Bay cities we had a splendid market both fancy and common. I figured my hens netted me $2.00 each and ducks $7.00 each a year.

I brought my San Francisco winners and record-breakers down to San Luis Obispo county and after some months bitterly realizing the hopeless conditions, sold them to the Chinamen for forty cents apiece. Ducks that laid 230 eggs each per year, beautiful, ivory white, large and delicious.

Nothing wrong with ducks, but look out for your public!

THE PACKAGE SELLS THE GOODS.

Nearly everything we eat is nowadays sold in packages, excepting most fresh fruits and fresh eggs, which still are doled out by the pound or the dozen. Why is this?

Are poultry breeders wanting in enterprise in the exploitation of their products? Is it not just as feasible to build up a private trade for new laid eggs as it is for breakfast foods and family soap? It has always been a pet theory of ours that it is just as practical to create an egg and poultry route as it is a milk route.

Such routes are not unknown in the East; here and there poultry breeders in California carton their product with a guarantee as to quality and date the egg as laid. Wherever breeds have sufficient resource in the shape of laying hens, the plan has worked out; failure has invariably been due to a want of reliable supplies. The cost of cartons and labels need not exceed 3 to 5 cents per dozen, while prices received vary from 10 to 15 and 20 cents per dozen above ordinary store eggs. The carton label, which should seal down over three sides of the package, so as to avoid refilling by shrewd dealers, might be worded something like the following:

TWELVE NEW LAID EGGS
FROM THE
SUNSET POULTRY FARM
JOHN AND RICHARD DOE
GARDENA, CAL.

FOR PRIVATE TRADE ONLY.—Guaranteed to have been laid on the day stamped on each egg or package.

The side might state: That the poultry plant producing these eggs is clean, light and sanitary, and that the hens are pure blooded fowl, healthy and robust.

On one end state that the birds are fed nothing but wholesome foods—choice grains, fresh greenery, and pure animal foods, thus insuring the flavor and nutritious quality of the eggs.

On the other end state that if the seal of the package is unbroken, that the eggs it contains were laid on the date stamped on the shells. Invite inspection of your plant, and impress the public with the fact that you are in a position to carry out these promises.

Does the plan not look feasible? And if so, why not try it?

Every one engaged in raising poultry for profit should endeavor to take advantage of every source of profit. The value of poultry feathers is an important reason for dry-picking the birds. Dry-picked body feathers bring from 17 to 19 cents per pound, while scalded feathers are worth less than a cent a pound. The demand for feathers adds to the poultryman's profits.

The sunshine and fresh air should be able to reach every corner to destroy any germs that might be lurking in dampness. The fowls should exercise by scratching that they may cause a good circulation of the blood. The above are the three best medicines in the poultry doctor's art.

Don't put fifty fowls in a house built for half that number.

Timely Ranch Suggestions

SUGAR CONSUMPTION IN THE UNITED STATES.

The people of the United States consume half their own weight in sugar every year. This may seem a startling statement, but if we take the quantity of sugar produced in the United States and add to this the quantity brought from our own islands and the quantity imported from foreign countries, and subtract therefrom the amount exported, we get a grand total of considerably more than 7 billion pounds consumed in the country; and by dividing the population into this grand total, we get an average of 81½ pounds per capita, speaking in round terms, for 1910, and about a like quantity for 1909. It is not assumed, of course, that each person necessarily consumes sugar equal to one-half his individual weight; but taking the total consumption and comparing it with the total population in the section known as continental United States, the average yearly consumption of sugar is found to be about 81½ pounds per capita.

In fact, the people of the United States are larger consumers of sugar per capita than those of any other country of the world except England, for which the latest figures show a consumption averaging 86 pounds per capita, against our own average of 81½ pounds per capita. The next largest per capita is in Denmark, 77¾ pounds; followed by Switzerland, 64 pounds; Sweden, 54 pounds, and Germany and Holland, each about 43½ pounds.

Not only is the United States the second largest sugar consumer per capita, but the total amount consumed annually is much greater than that of any other country, aggregating, as above indicated, more than 7 billion pounds per annum, against about 4 billion pounds in England and about 3 billion pounds in Germany.

About one-half of the sugar consumed in the United States is brought from foreign countries, about one-fourth from our own islands, and the remaining one-fourth is produced in this country. The total production of sugar in the United States now amounts to 1¾ billion pounds a year, of which more than 1 billion pounds is beet sugar and about three-quarters of a billion cane sugar. It is only recently that the production of beet sugar in the United States has come to exceed that of cane sugar. In 1900 domestic production of cane sugar was twice as great as that of beet sugar, and 20 years ago was more than 60 times as great; but the growth of beet sugar production has been very rapid in recent years, and in 1907, for the first time, exceeded in quantity that produced from cane and has so continued since that time.

Of the sugar brought from other countries, nearly all is made from cane. While about half of the world's sugar is made from beets, most of it is produced in Europe and consumed in the country of production or in other parts of that grand division, while most of the world outside of Europe obtains its sugar supply from cane, grown of course, in the tropical and subtropical sections. Of the cane sugar which we consume, most of that coming from foreign countries is drawn from Cuba, the Dutch East Indies, and smaller amounts from the West Indies, Mexico, Central and South America. All of that coming from our own islands—Porto Rico, Hawaii, and the Philippines—is cane sugar, while of the domestic product about forty per cent is produced from cane. The beet sugar of the United States is grown chiefly in Colorado, California and Michigan, and some in Utah, Idaho and Wisconsin; while most of the cane sugar is produced in Louisiana, with smaller quantities in Texas, Florida, Georgia and South Carolina.

The sugar "habit" is evidently a growing one with the people of the United States and probably with those of other countries, since the total world production of sugar, including all countries for which statistics are available, has increased fifty per cent in the last decade and about doubled in 15 years. In our own case the consumption has shown a rapid growth, the per capita consumption having been, in 1880, 40 pounds; in 1890, 51 pounds; in 1900, 59 pounds; and in 1910, approximately 81½ pounds.

What is the cost of this enormous quantity of sugar consumed in the United States? This is more difficult to answer. The valuation of that brought from foreign countries and our islands is set down at about 175 million dollars in 1910, and the stated value of that produced in the United States, at approximately 75 million dollars; though this comparatively high figure when considered by the price per pound, is due to the fact that the valuation is based upon the refined article, while that of the sugar from abroad is the value of the unrefined article in the country of production. If, however, we accept a general average of five cents per pound as the retail price paid by our people for the 7 1-3 billion pounds of sugar consumed by them in 1910, we should get a total of $366,000,000, or an average of approximately $1,000,000 a day paid for sugar by the people of the United States.

SOME POPULAR PROVERBS.

Proverbs contain the condensed wisdom of the ages. The man who can phrase a proverb that takes hold of the popular imagination and retains it, wields an influence long after he has been forgotten. It is essential to a proverb that it be easy of comprehension, that it strike the popular fancy, and that it be capable of various applications.

It is easy to remember a proverb; it is not always easy to remember the application. Take, for example, the proverb, "Don't bite off more than you can chew." Many a farmer recognizes its wisdom, its force, but keeps on buying more land than he can pay for, renting more land than he can farm, farming more land than he can farm properly, keeping more cattle than he has grass for; at every stage of the game biting off more than he can chew, undertaking to do more than he can do well and profitably.

Few proverbs, however, express the whole or complete truth. Most of them express only half truths. The following are examples: "Don't put all your eggs under one hen." Don't confine your farming operations to one crop, whether that be wheat, oats, corn or rye. In other words, rotate your

THE EASIEST WAY TO INSURE THE EFFICIENCY OF YOUR IRRIGATION SYSTEM . . THE efficiency of your irrigation system depends on the efficiency of the engine that operates it. You may not need to use it for months, but when you do need it, your need is urgent. It means actual financial loss then if it doesn't work. Bear this in mind when you select your engine. Pick out one that is a known quantity—not an experiment.

I H C Gasoline Engines are always a safe selection. Their efficiency has been proved. They have years of success behind them. There are thousands in use.

I H C Gasoline Engines

are made in all styles and sizes—1 to 45-H. P.—vertical or horizontal—stationary, portable, or traction. This makes it easy for you to get just the right type and size for your individual use.

Besides supplying power for your irrigating system, an I H C engine can be used for operating the feed grinder, fanning mill, thresher, separator, churn, washing machine, cider press, alfalfa cutter, etc.

If you will call on the I H C local dealer, he'll be glad to show you points of I H C superiority you ought to know about. Ask him for the I H C Gasoline Engine catalogue, or, write the nearest branch house.

T. THOMAS MFG. CO., 2723 Wayne St., Dayton, Ohio

crops. If one crop fails, another will win. There is wisdom in this proverb which the bonanza farmer would do well to heed, wisdom which the wheat farmer in Kansas, the corn farmer in Illinois or Iowa, will disregard at his peril.

The other half is found in such proverbs as these: "Don't scatter your shot," "Bunch your hits," "Master one crop, one book, one subject thoroughly. The real wisdom of the farmer is to have the main crop that for which his land is best adapted; then other secondary crops which will spread his energies over the year and diversify his resources.

Problems of heredity and environment are favorite subjects for the makers of proverbs. For instance: "Get a cat of a good kind," "Like father, like son," "The fathers have eaten of sour grapes, the children's teeth are set on edge." All these emphasize the importance of heredity, the law that runs through nature, that like produces like. This, however, for the farmer is only half the truth.

The other half is expressed in the proverb, "The breed goes in at the mouth," or "the corn-crib cross." The man who follows this exclusively will make a mistake. He should realize that it is intended to express only a half truth. It is not possible by any kind of feeding to make a first-class animal out of a scrub. The "corn crib cross" will greatly improve the scrub, but it will not make it a first-class animal. On the other hand, no matter how well-bred an animal is, how excellent its sire and dam, its grandsire and grand-dam, its great-grandsire and great- grand-dam, unless it has the proper feed and proper environment it will gradually retrograde.

We mention these proverbs to set our readers to thinking and studying the meaning of the proverbs that are floating around in their community. Always find out whether a proverb expresses a whole truth or a half truth. It will generally be found to be a half truth.—Wallace's Farmer.

THE POSTAL DEFICIT.

The remedy for the postal deficit is good business management, divorced from politics; and there is no other remedy. Tinkering with it by complicated and discriminating patchwork legislation is simply dodging a plain duty and is adding more complications to an already complicated wrong method.—Don C. Seitz in the World's Work for February.

Farmers are accomplishing great things for themselves by different forms of co-operative effort in Ireland, England, Germany, France and Denmark. There are many people who ridicule the idea that the farmers of this country, as a class, will ever be able to accomplish much by organization. This is certainly placing a low estimate on the ability of our farmers and on the training that comes to them through the exercise of self-government. One of the qualifications for success in modern life is the ability to work with others for the attainment of common ends. When the American farmer feels the need of this he will acquire the faculty in a hurry.—Agricultural Epitomist.

There are sixty-five factories in the United States making sugar from beets. Yet there is room for many more such factories, for the home output does not equal the demand and much sugar must be shipped from countries outside the United States.

Questions and Answers

THE EDITOR AND STAFF

Questions to be answered in this department should be received at this office one week before reply is expected. Write plainly on one side of the paper and sign full name and address. Unsigned communications receive no attention.

Best Dairy Breed.

Which is the best breed or strain of stock for dairy cows. I am undecided whether to choose Durham or Holstein, or is there a still better breed? I wish to keep from ten to fifteen cows. Will have more or less range. Will keep hogs and chickens and wish to raise calves for veal. Of course, cream is the principal factor, and I prefer strong constitutioned cattle.—A. N., Paso Robles.

Either of the breeds selected will fit the conditions named. The idea of using pure-bred animals has not come into your mind probably. I should certainly have a registered bull and a couple of registered heifers if not all registered stock. The idea then of selling veals can be dismissed and the animals will sell rapidly at fifty dollars each, for breeding purposes, instead of eight or nine for butchering. The cows are usually called cows rich in butter fat, not cream, as that may mean anything from 12 per cent to 40 per cent butter fat. With ten or fifteen cows a small separator should be used and then the calves will do nearly as well on skimmed milk as on the whole milk. Now the cows must receive all they can convert of food into butter fat and milk at all times. While the range is good, still heavy milking fresh cows make very few steps answer their purposes. The cows are, therefore, best corralled and fed and the young growing stock kept on the range as much as possible. If a month before the heifers freshen they are put in with the cows they become gentle and used to going with them. If the heifers are allowed to calve out in the fields they are much harder to handle. The healthiness of the cows depends on the feeding and care they have received and if only tuberculin tested cows are purchased there cannot be any diseased ones in at the start.—M. E. S.

Onions.

Which are the most productive onions for this section and how should they be planted? Which is best to use, seeds or sets?—C. M., Arroyo Grande.

The best onion for your section is the Brown Australian, seed for which may be planted and later thinned to proper distance, using plants taken out to set other rows if desired, or plant by sowing seed in beds and transplanting all to rows later. Planting in rows and thinning is probably cheaper. There is very slight difference in time of ripening of seeds and sets, and the seeds are of course much cheaper.

Oranges Without Irrigation.

I notice in daily papers reference to an orange grove in San Bernardino county which was doing well without any irrigation, simply being thoroughly cultivated. Can you give me the method of handling such an orchard, and is it advisable to plant oranges where there is no irrigating water?—Subscriber.

Such a question cannot be answered positively for the reason that soil and sub-soil conditions must be understood to know how much of a possibility there is of securing and conserving the natural moisture. We have never yet heard of an orange grove that bore any material amount of fruit and brought it to merchantable size unless irrigated. It is possible to bring young trees up to bearing age if the soil conditions are favorable, but the planting of an orange orchard where there is no possibility of irrigation would, we think, be unwise.

Bermuda.

What is the best and cheapest method of eradicating Bermuda, by some called salt grass? It is a great nuisance, especially in irrigating ditches in which the seed ripens and is later carried over the land. It is especially perplexing in alfalfa fields. We must eradicate it.—Subscriber, Imperial.

The only way of eradicating Bermuda satisfactorily is by thorough cultivation. It surely is a most perplexing problem along ditches. Chemical methods have been tried and both because of expense and indifferent results have been usually put aside. Railroads have used gasoline burning contrivances, but we never heard of their successful operation along ditches. The use of low-grade distillate sprinkled over the grass on a hot day will have some effect in reducing the pest, but this, of course, must be continually repeated. Any subscribers who have any light upon this subject will confer a favor on many if they can give more explicit information.

Pruning Grapes.

I have a seven-acre vineyard of Muscats near Selma. At present it is growing only brush and practically no grapes. When three years old the seven acres bore three tons, but since then only about a ton. They are troubled with thrips. There is abundance of bloom, the land has good care, is irrigated once in the season and afterwards thoroughly cultivated to hold moisture. When is the best time to prune? Does it injure the vines to bleed after pruning?—Subscriber, Selma.

If these vines are given a little more room by leaving one bud more on some of the spurs they may set fruit better. If the fault is in the pollination, planting a few rows of Palomina vines will help greatly. The Palomina is a vine grape that bears white grapes of good quality. It is a profuse bloomer and has a dry pollen that is carried well by air and wind. The Muscat has a waxy pollen that does not carry well in damp weather. —M. E. S.

Mange.

I read some time ago in The Cultivator a formula for curing mange in calves. My paper has been destroyed. Will you please give me a remedy. Have a horse badly affected. Hair comes off in spots which become sore and scabby and seem to itch terribly. J. O. S., Parlier.

The difficulty with curing mange is in reaching it, as the burrowing insect that causes the trouble secretes a waxy-like substance that keeps the remedies from reaching him. The first thing to do is to remove this waxy coat. Take kitchen soap and slice it thin, put into warm water to dissolve. Add to each pound of soap a pint of coal oil, stir or beat it into the soft soap. Then start in by covering the places on the horse with the soft soap, let it remain on five minutes, then soak it off with hot water and repeat until the hardened surface is removed. Then cover the places with either tar oil or with a mixture of lard and sulphur mixed at home. Repeat this

SWIFT'S

ARSENATE OF LEAD

For

Codling Moth, Canker Worm, Bud Moth, Pear, and Cherry Slug, and all leafeating pests.

Perfect Protection

One orchardist writes that after using Swift's Arsenate of Lead, he found but sixty-four apples affected by the codling moth out of 1141 boxes, or 1-200 of 1 per cent.

Does not scorch or burn no matter how strong it is used.

In 1 lb., 5 lb., 10 lb., 20 lb., 50 lb., and 100 lb. packages.

WINSEL'S GARDEN CALENDAR

FOR THE MONTH OF FEBRUARY

FRUIT TREES. Plant Oranges, Lemons and Grape Fruit. Deciduous Trees can still be planted this month, Peaches, Plums, Apricots, Almonds, Apples, Pears, Figs, Persimmons, Walnuts, Berry Plants and Grapes. Send your orders to 211 South Main Street, or visit our nurseries, S. W. Cor. Washington and Figueroa Streets, Los Angeles, and select your trees. We have a fine assortment, and our trees are extra large. Send for price list.

FIELD GROWN ROSES. Two-year-old. We have a complete assortment of varieties best adapted to Southern California. Price 35c each, $3.50 per dozen. Freight prepaid to any point in Southern California on orders of one dozen or over. Send for our Rose List.

VEGETABLE GARDEN. Sow Peas, Beets, Carrots, Cabbage, Lettuce, Parsnips and Radish. Plant Onion Sets, Rhubarb Roots, Cabbage and Cauliflower Plants, Shives, Horseradish, Tarragon and Asparagus Roots. On the Hot Beds, sow Egg Plant, Tomato and Pepper Seeds.

LAWNS. Put in your Lawn with our Kentucky Blue Grass and White Clover Seeds. We carry the best grades only.

FLOWER GARDEN. Sow the seeds of Asters, Sweet Peas, Coreopsis, Centaurea, Alysum, Poppies and Pinks. We have on hand the following plants that can be set out now at 25c per dozen, $1.50 per hundred: Gaillardia, Verbena, Pansies, Violets, Stocks.

SHEEP MANURE. Free of weeds and odorless. Gives immediate results. Delivered anywhere in Los Angeles, Pasadena or Hollywood for $2.25 per hundred pounds.

LANDSCAPE GARDENING. Estimates and Plans furnished.

OUR FREE CATALOG. Giving directions how and when to plant everything. The new 1911 issue will be out about the 15th of February. Send in your name NOW for a copy.

STRAWBERRY PLANTS

75 per cent of the strawberries sold in Los Angeles last season were **KLONDIKE BERRIES** 90 per cent of the strawberries shipped last year were **KLONDIKE BERRIES.** Why? What plants are you going to set out.?

E. H. LEARNED ***R. F. D. No. 5, Los Angeles***

Grower of Strawberry Plants only, and only the best.

treatment of washing and soaking off the waxy coating after three days and again cover heavily with the lard and sulphur. These cases are stubbon to heal and the hair should be cut around the spots very short so that there may be none hidden away in under it. When the trouble is cured or if at any time the surface becomes sore, omit the soap and wash well with warm water, and coat with plain lard until the irritation subsides. The curing of mange, like itch on the human body, is by keeping everything clean around the animal, for when it is cured it may be reinfected from the sides of the stalls. We use on our stalls a mixture that is very cheap. Take crude oil and thin it enough with engine distillate to spread with a whitewash brush. Go over the entire surface of the walls with this wherever the animal rubs. Repeat every little while until the animal is well.—M. E. S.

Warbles.

On taking up heifers from pasture I find their backs lumpy. Neighbors tell me this is from grubs. Can you prescribe?—G. W., Fresno.

These lumps are caused by warbles, a common grub which infests cattle in all sections. They can be forced out by pressing with the thumbs or some kill by injecting a very few drops of coal oil, using the ordinary tin oiling can. A small hole will be found through the skin over each of the grubs and through these the oil can be injected.

Planting Near Pepper Trees.

How near to pepper and cottonwood trees is it advisable to plant orange and olive trees?—W. E. H., Hemet.

This would depend somewhat upon soil conditions, size of the trees, etc. We have heard orchardists say that they have seen pepper and eucalyptus trees affect the bearing of oranges 100 or more feet from them. If the soil is given abundance of manure and a large sub-soil plow is run to cut the surface roots of the peppers, it is very probable good results might be secured from fruit trees. In any case it is a continual fight, especially if the tops are large, for in that case the draft is still greater on the soil moisture and fertility.

Indian Runner Ducks.

We have eleven ducks which began laying in November. In a short time they produced eight eggs per day. Later they dropped to four or five. Now we are getting six and sometimes eight. We are at a loss to know why they do not lay better. They lay a very large white egg, superior for cooking, yet the market classes them as No. 2. Is there any market where they will bring the same price as hens' eggs? Are ducks as profitable as hens as egg producers?—Old Subscriber, Santa Rosa.

We do not think this shrinkage should cause you any concern during these cool months, and think it a perfectly accountable condition. With proper feed conditions the spring months will bring egg production up to normal. It is an unfortunate, and we believe unfair, discrimination in the market against duck eggs, but so far as we know it prevails in all markets. As to the profitableness of ducks, would refer our subscriber to article by Miss Stocker on poultry page of this week.

Rabbit Troubles.

Have lost several two-months-old rabbits. Hair comes off under chin; also froth at mouth.—Subscriber, Martinez.

The loss of hair in young rabbits is perhaps due to some sort of parasite. Chick mites play havoc with them, and it would be well to anoint with carbolic salve, perhaps adding a little kerosene, for good measure. The frothing is a form of indigestion, the writer does not say how they are fed, but I suspect the green food, which is not always as fresh as it should be. Give only very dry bread, if toasted, so much the better, or wheat that has been browned in the oven. Too great care can not be exercised in seeing that green feed is always fresh, and not wet with rain or dew.—B. J. O. M.

Casabas Splitting.

Have planted casaba melons for the last two years and they all split before ripening. Do not irrigate. Have planted in all kinds of soil and it seems to make no difference. Is there any special kind of casaba that will grow without splitting?—Subscriber, Neenach.

This is a new complaint against the casaba. Splitting is especially characteristic of one or two varieties of melons, but has not been reported before as a serious factor with the later ripening varieties. The only explanation we can offer is that possibly the difference in temperature between night and day is great. Cold nights and warm days will cause the splitting. Irrigation may also cause it, but in the present instance that is not the case.

Apple Seed.

What is the best kind of apple seed for growing stock for grafting?—Subscriber, Colusa.

The usual source of seed is the pomace of the cider mill which of course gives seeds of all kinds of health and vigor. Where one can do so, seed from apples growing on largest and thriftiest of trees will in all probability give strongest growing stock.

Grafting Plums.

I have 80 large plum trees mostly of Japanese variety which I wish to graft over to American varieties. Neighbors tell me it cannot be done successfully, that I cannot get good union.—Subscriber, Vorden.

Plums are more easily grafted than most other stone fruits, and we doubt not you can successfully change over your trees if the work is carefully done.

Curing Olives.

Please give recipe for curing olives. —Subscriber, Ramona, San Diego county.

The formula is too long to give in these columns so we refer our subscriber to Mrs. Sherman's extended instructions on page 244 of the issue of The Cultivator of September 15th last. That is declared to be one of the best methods ever given for handling olives.

Bermuda.

I enclose specimen of grass which has appeared in alfalfa. What is its name and nature?—S. L. U., Ontario.

The subscriber sent in only roots and one or two spears which had become dried so it is impossible to be sure, but there is little doubt that it is Bermuda or joint grass. Another name often applied, which also expresses its nature, is "devil" grass. It is a serious pest in alfalfa and practically the only method of eradicating it is to plant other crop which will permit of clean culture for a year or two.

Veterinary

Answers in this column by Dr. Fred G. Matthews, are without charge. For immediate mail answer remit $1.00. In writing questions give full symptoms or particulars of injury of animal.

Bloating in Cows.

Is turpentine good for bloat in cows—what is the proper dose and how administered? What other simple remedy is good? What value has bicarbonate of soda in this disease? Can bloat be reduced by means of a garden hose passed down the throat? How should the trocar be used?—Subscriber.

Turpentine given in doses not exceeding two ounces, as a drench, and mixed thoroughly with a pint or more of raw oil, sweet oil or melted lard, is a safe remedy and one of the most reliable. It has the advantage of being a direct stimulant to the stomach and a general stimulant to other organs.

One pound of epsom salts, a half teacup of table salt, and a tablespoonful of strong red pepper pulverized mixed in a quart of water and given as a drench is also an excellent remedy, usually reducing the bloat in about thirty minutes.

Baking soda (bicarbonate of soda) is seldom used for this purpose by practical veterinarians.

I would not recommend the garden hose. Often almost incredible amounts of fluids may be syphoned out of the stomach by the use of the stomach tube, the introduced end of which usually remains imbedded in the liquids and the food in the stomach, hence the gas which rises above this mass is not reached.

The trocar affords the quickest means of relieving bloat and its use, even in the hands of farmers, is accompanied by little danger. Select the point of highest distention, which is usually about four or five inches in front of the angle bone of the hip; hold the trocar in place with the left hand and strike it a firm blow with palm of the other hand. Now grasp the protruding part with the thumb and finger of the left hand and withdraw the stilet with the other. Retain the hold on the tube while it remains in place in order to steady it. When all the gas has escaped reinsert the stilet and withdraw the instrument. Always give one of the drenches recommended to check further production of gas.—F. G. M.

Summer Itch.

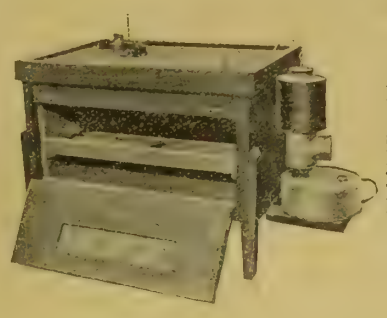
There is some kind of itch spreading over the neck and sides of my horse. Have noticed it coming on for about two years. Is this mange?—Subscriber, Riverside.

A microscopical examination would be required to determine whether this is some form of mange or eczema. Mix liquid sulphur and sweet oil, equal parts, shake thoroughly and rub into the affected skin every third day.

Worms in a Dog.

I am sending under separate cover a specimen of worms which my collie pup has been passing with her stools. She is active and apparently well, but thin, though ravenously hungry and well fed.—Subscriber, Morgan Hill.

The specimens submitted appear to be segments of the melon-seed tape worm. Mix five grains each of santonin and calomel and divide into ten equal powders, then after having starved the pup twenty-four hours, give one powder every two hours till four are given. Follow two hours after the last dose with two tablespoons of castor oil. Repeat after ten days.—F. G. M.



Success Incubators

This is a true photo of the 1911 style 60-egg hot water copper tank, automatic Success Incubator. Made the same as all Success Incubators with double walls, packed top, slatted egg trays, and the best hot water heater made. Send today for the **FREE** 48 **Page Catalog.** Contains the most interesting poultry lectures ever written.

Fireless Brooders

$3.00, $5.00 and $6.50

We pay the freight. Send today for full description of them. They will raise stronger and better chicks than any heated brooder device ever made. Our prices on all Incubators and Brooders are many dollars less than others ask. See these prices.

60 Egg Size, $9.00; 130 Egg Size, $14.00; 360 Egg Size, $25.00; 612 Egg Size, $40.00. We pay the freight.

75 Chick Indoor Fireless Brooders, $3.00; 150 Indoor, $5.00; 150 Outdoor, as shown in cut, $6.50. We pay the freight. Write us today.

We manufacture and sell at wholesale rates. You do not pay us any agent's profits. When you buy from an agent you lose 25 to 30 per cent of the price you pay as that is their profits. Buy from us and save that money. Investigate today.

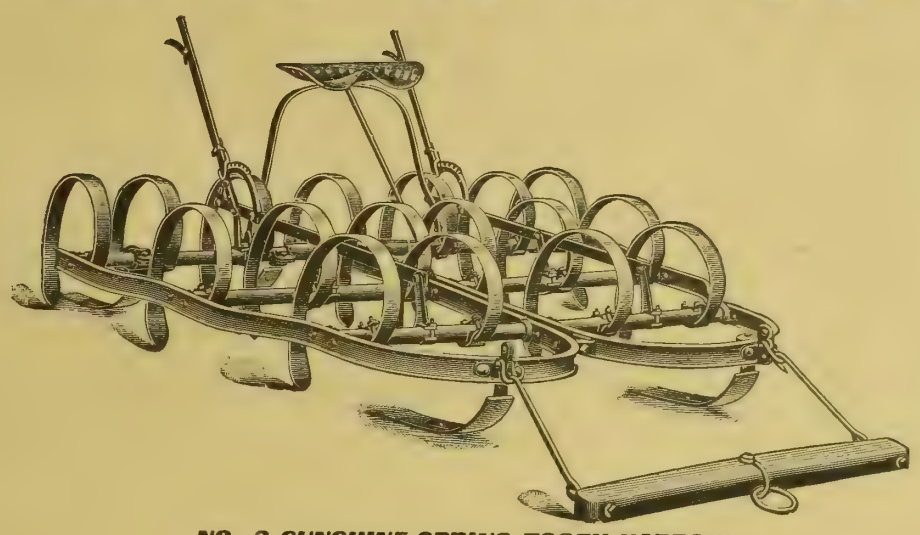
HARROWS



NO. 3 SUNSHINE SPRING TOOTH HARROW

The main frame is made of double I steel of high carbon, made narrow in front so as readily to pass obstructions.

Cross bars are 1¼ inch structural tubing, and have no holes drilled through them, compression clamps instead of bolts being used for fastening. The full strength of the bar is thus preserved.

Teeth are 1¾ inches wide, ¼ of an inch thick, and 44 inches long, made of the best quality of spring steel and are warranted against imperfections. The teeth pass under the bar and are held by a compression clamp—no holes through the teeth to weaken them.

Furnished in sizes from 5 to 12 feet, mounted on runners as shown in the catalog, or mounted on wheels.

Our stock of Sunshine harrows is large and each style is particularly constructed for California conditions. The line includes Spike Tooth, Spring Tooth, Single and Double Disc Harrows. Please write for full particulars.

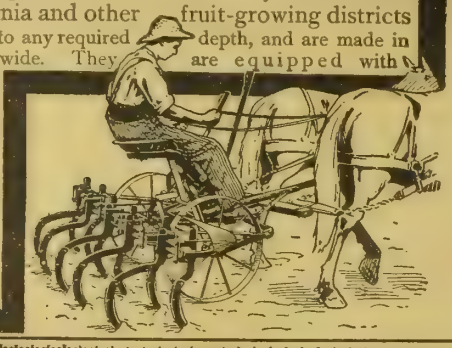
Planet Jr.

No 41 Orchard and Universal Cultivator

Adapted especially for the work of orchardists and vineyardists. Does quicker and more thorough work than any other implement made for fruit-growers' use. Planet Jrs were invented by a practical farmer who felt the need of just such implements. They are backed by over 35 years' manufacturing experience, and are used by thousands of orchardists throughout California and other fruit-growing districts

They furrow, hoe, and cultivate to any required depth, and are made in sizes which work up to 7 ft. 9 in. wide. They are equipped with side-hitch and fruit and tree shield. Can be changed to a disc-cultivator. High-carbon steel frame, steel tongue, low wheels enclosed by the frame. Strong, substantial, easily handled.



We carry stock in San Francisco.
Agencies in all principal Pacific Coast cities. Write for name of nearest agent, also illustrated 56-page catalogue of all 1910 Planet Jr implements. Free and postpaid.

Irrigation and Forestry

FOR SETTLEMENT.

More than 1,000,000 acres of agricultural, grazing and timber lands will be available for homestead purposes as soon as the Colville Indian reservation, north of Spokane, Wash., is opened to settlement, according to Clair Hunt, alloting agent in charge of the apportionment of the reserve land. While at Spokane recently Mr. Hunt said:

"There are 2250 allotments to be made and the Indians are choosing chiefly agricultural and grazing lands. This will take 300,000 acres of a total of 1,400,000 contained in the reserve, leaving 1,100,000 acres that will belong to the people.

"Much of this will be first-class agricultural land and a large part of it will be covered with some of the finest timber in the state of Washington. A few of the Indians have shown a disposition to take land in the timber regions.

"The Colville Indians are good agriculturists and grow all kinds of grains, fruits and vegetables. Some of the finest peaches raised in the state of Washington are grown on reservation lands. The Indians are peaceable and friendly to the whites. They are industrious and thrifty, and only a few of the older men, who are incapacitated for work, require aid from the government."

Mr. Hunt added that while no date has been fixed for the opening of the reservation, it is likely this will follow soon after the allotments have been made to the Indians. Much of the preliminary work of assigning lands has been completed. The work is progressing and with the arrival of another agent and additional help it is expected to complete the assignment and allotment in short order.

BLOWING OF SANDY SOILS.

Sandy soils are especially liable to damage by blowing, not only because of their low natural cohesion but also because they are usually well drained and retain water poorly in the surface layer, and hence lack the surface moisture which is a great preventive of blowing on soils composed of finer materials. The danger of blowing must always be borne in mind in reckoning the value of sandy lands and in designing for them a proper system of cropping. On them, as on others, the proper adjustment of the cropping system is frequently all that is necessary to prevent blowing. The principles which must govern its design are not essentially different in the case of sandy soils from those for soils in general. It should be noted, however, that the possibility of letting the stubble of one crop stand until the ground is ready for the next is more common on sandy soils than on others. Such soils absorb water readily, and the main reason for fall plowing, namely, the increase of ability to absorb mois ture, is in their case absent. The use of windbreaks offers also no new problems on sandy soils. Whether they are to be used or not used will be decided by factors with which the texture of the soil has little to do, except that of course this texture may be the cause of the trouble which makes some method of control necessary.

Aside from the cropping system, and in case windbreaks are not advisable, the main control method which is applicable to sandy lands is the increase of humus by the addition of organic matter, such as manure or straw or by the plowing under of some green crop. Sands are frequently deficient in humus, and its addition not only aids in preventing blowing but increases the usually low water-holding power and betters the general structure of the soil. Cases are rare in which sandy soils do not need humus, and their cultivation should always be so carried out as to increase this constituent. Blowing may frequently be prevented by this means alone.

The methods of cultivation (rolling, and the maintenance of a rough surface) advocated for decreasing blowing in general are of little use on sands. The cohesiveness of sand is slight, even when packed, and the formation or preservation of clods is nearly always impossible. Furrows run transverse to the wind may be occasionally of use, but are at best a minor means of control. This is true, also, of artificial moistening. Water runs so quickly through a sandy soil that it is usually impossible to keep the surface moist unless the whole soil is saturated—a procedure manifestly impossible if the land is to be used.—Bul. 421, U. S. Dept. Agr.

HORSEPOWER.

Will you be so kind as to explain what is meant by horsepower as applied to machinery? The dictionary says: "That unit of power of work of a steam engine, 33,000 pounds lifted one foot in one minute." That may be very clear but I do not understand it exactly.—B. J. O., Anderson.

The definition of horsepower given by the inquirer is of course very condensed. To explain more clearly the meaning of horsepower we quote at some length from Bailey's Cyclopedia of Agriculture as follows:

"The unit for measuring work is the foot-pound, and may be defined as the overcoming of one pound of resistance through a distance of one foot, or, as the lifting of one pound one foot. A horsepower is equal to the accomplishment of 33,000 foot-pounds of work in one minute, and is the customary unit applied in designating the power of a motor. The term 'horsepower' is an abstract mathematical unit and bears no fixed relation to the amount of work a horse is capable of doing. In fact, few horses are capable of doing more than two-thirds of a horsepower of work for any considerable period, though their maximum effort for short periods may be greatly in excess of this amount, as stated above. It has been found by experiment that the average sized man can do one-tenth to one-eighth of a horsepower of work, covering the usual working day of eight to ten hours. For a few minutes he can do half a horsepower, or a full horsepower for a few seconds.

"In changing from animal to mechanical power, experience would seem to indicate that these statements in regard to the power of animals are incorrect, inasmuch as it requires a motor of six or seven horsepower to do the work usually performed by three horses in handling farm machinery. The reason for this apparent discrepancy is found in the fluctuations of the load. On an average the load may be only two or three horse

power, but occasionally runs as high as six or seven. The horse can exert enough additional power for short intervals to get over these high places, while an engine, unless large enough to meet maximum requirements, will get stalled. Therefore, in replacing animal power with mechanical, it is best to install an engine capable of meeting the maximum requirements of the work in hand. In addition to this, there must be taken into account the amount of power required for traction if the engine is self-propelling.

"Professor King states the amount of power for hauling as follows: 'The hauling of two tons on a wagon at the rate of 2½ miles per hour, under the varying conditions on the farm, requires the team to develop energy at a rate ranging from 1.13 horsepower to as high as 4.98 horsepower.' In stubble plowing when the soil is in a medium condition, Professor King finds that two 1600-pound horses find their full capacity for work taxed by the 14-inch plow cutting four to five inches deep, while a team of 1200-pound horses find sufficient work in hauling a 12-inch plow cutting the same depth of furrow."

FERTILIZERS SHOULD BE TRUE TO ANALYSIS.

A fertilizer case was recently tried in an English court, the details of which ought to interest our farmers. It seems that in England there are small mixers or manufacturers who buy up refuse at slaughterhouses and mix with potash and phosphates. Then they sell the mixtures at low prices as special crop manures. They do a small trade, but are not expert chemists, and usually make a rough mixture without the improved machinery used by the large manufacturers. One of these dealers sold a mixed fertilizer to a farmer, guaranteeing that it contained two per cent of potash. Analysis showed that it contained less than half of one per cent, and the farmer sued for damages. The farmer proved that the goods were what he bought under guarantee, and the chemist proved his analysis. For a defense the manufacturer claimed that, while the potash was short, the nitrogen and phosphoric acid were in excess, so that this extra value more than made up for the shortage of potash. The farmer admitted that he used the fertilizer, but that he could not yet tell what the result was. In brief, his claim was that he ordered potash under guarantee, and did not get it. The judges imposed a fine of $25 and costs, or over $50 in all. Under the English fertilizer law, therefore, the dealer cannot justify a low analysis in one element by showing an excess in others. In this country some manufacturers cover this point by stating with their guarantee that extra value in nitrogen, for example, shall be considered to make up shortage in phosphoric acid. We do not regard this as fair, for the excess of one could not possibly make up for the other. The lesson from this English case is to buy fertilizers from the larger and more careful manufacturers, since their goods are more likely to be carefully and evenly mixed.—Rural New Yorker.

The great majority of the people of Imperial Valley have united in the effort to establish an irrigation district under the Wright-Bridgford act to take over the holdings of the California Development Company.

Here is Another Electric Driven

AMES PUMP

We make Pumps for every service where the source of supply is either a Bored or Dug Well and the lift is from 20 feet to 2000 feet to the surface.

With a lift of from nothing to 2000 feet above the surface through from no pipe to 20 miles of pipe above the surface, an Ames Pump will deliver a continuous stream from lower end of cylinder in well to point of discharge. Write for our catalog.

Berry Plants—Logan and Phenomenal, $2.50 per hundred. Himalaya, Dewberry, Mammoth and Gardena Blackberry, $1.50 per hundred. H. O. Sorkness, Hemet, Cal.

MACHINERY.

ATTENTION, FARMERS!

120 Horsepower Pumping, Lighting and Power Plant, composed of two 60-horse gasoline or distillate engines, with Westinghouse generators, switchboard, circuit-breakers, storage batteries, etc.

In addition we can furnish four 20-H. P. D. C., one 10-H. P. D. C. and two 7½-H. P. D. C. Western Electric motors. All of these are in first-class condition, having been overhauled at our works.

Just the power for pumping several wells at a short distance from each other. We will sell one unit of 60 H. P.

This plant cost new $10,000, but we will sell complete for $4,000. The generators alone cost $2000. We can supply any extras as we have all the patterns of the parts. Will make prices on motors in proportion to the above.

Also one R. & V. 6-H. P. vertical gas engine, new, and one new 18-inch single-acting Addison pump head and cylinders. Price $360.00, which is 25 per cent discount on lowest purchasing price.

Do not miss this chance.

Axelson Machine Co., Wyse and Ann Sts., Los Angeles, Cal.

For Sale—Windmills, pumps, engines, piping, brass cylinders, guaranteed first class, wagons, buggies, harness, plow scrapers. Power feed cutters, 10 tons 12 lb. T rail dump cars, 20 H. P. self-contained hoist brand new. Sundries too numerous to mention.

5 H. P. Pumping Plant

Special sale 5 H. P. engine jack, 5-inch pump, belting, engine house, 6000 tank and 24 ft. stand $235. This is not junk, but running now. Cost double new. 2 H. P. pumping plant, engine, jack, pump 2000 tank nearly brand new very cheap. Also 10,000 gallon tank, 34 ft. stand, fancy cover, $90, only used one year. Also 5-ton brand new mower, hay rake, parts such as knives, guards, sickle guards, connection rods, 100 complete sets rake teeth. We will sell these fittings at 50 per cent off 1st price or wholesale in lots to suit. Checks accepted. Call, write office of Demmitt Co., 120 North Main St., Los Angeles, Cal.

For Sale—A good portable drilling rig, good for 800 ft., complete string of tools. About half its value, at $750.00. Address M. H. Magie, 1242 Harvard Blvd., Los Angeles, Cal.

For Sale—A practically new No. 2 Sharples Separator. Snap. C. P. Dandy, 421 Wilcox Bldg., Los Angeles.

For Sale—9 H. P. portable gas engine on steel trucks. Almost brand new. Price right. Bailie & Brandt Co., 943-945 N. Main St., Los Angeles.

For Sale—Double acting deep well pump and cylinder in fine shape. Cheap. Machinery Exchange, Main & Bruno Sts., Los Angeles.

Fertile eggs for hatching. Choice varieties. White Rocks, White Wyandottes and White Orpingtons at $1.50 to $4.00 per setting; $6.50 to $10.00 a hundred. Ducks—White Muscovy, Dark Muscovy, White Indian Runner, White Pekin, Buff and White Orpington, $1.00 to $3.00 a setting; $5.00 to $12.00 per hundred. Send for Circular. Pheasants' eggs in season.

WICK'S FOWL WHITE FARM, Moorpark, Cal

Business

EVERY FARMER CAN HAVE RUNNING WATER.

The one big advantage usually claimed for the city is running water where needed. There is no good reason why nearly every country place should not enjoy similar advantages in house and grounds and have water for irrigation and the many other uses to which running water can be profitably put.

There are few places not located within a mile of a stream or pond. With a fall of two feet or over a hydraulic ram can be installed to pump to a height of thirty feet for every foot of fall. It will work day and night without attention. The operating expense will be the renewal of rubber valves every year or so.

The Rife Engine Co. claim a pumping efficiency for their Rife ram of 60 per cent to 90 percent, depending on ratio of fall to pumping head. Any size ram, pumping from three to 700 gallons a minute can be obtained.

By addressing the Rife Engine Co., at 111 Broadway, New York, catalogues, complete plans and estimates for any place will be gladly furnished free.

MORE PROFITS BY GIVING COWS AND POULTRY BETTER SHELTER.

If more farmers would seriously take into consideration the amount of profits they forfeit every winter from poorly housed stock, they would lose very little time in remedying any such evil that exists on their own farms.

It has been conclusively proven that cattle and poultry when housed in dry quarters, free from dampness and intense cold, keep in a far healthier condition than under less favorable conditions.

Cows keep weight and give larger yields and richer milk, and hens lay far better when good shelter is afforded them.

The cost of properly fixing up the quarters is not so great as would at first be supposed. No heating is necessary, and if the stables and poultry houses are in fair condition, all that is necessary is a good, sound, substantial roofing.

Because Genasco Ready Roofing is moisture proof and a non-conductor of heat and cold, and gives lasting protection it is better adapted for this purpose than any other roofing, and it costs no more.

Genasco Ready Roofing is made of genuine Trinidad Lake asphalt—the great natural waterproofer. It is not affected by rain, sun, snow, ice or any climatic condition.

Any handy man can easily lay Genasco Roofing—all the tools required are a hammer and a pair of shears.

If you don't know the dealer in your neighborhood who carries Genasco, write to the Barber Asphalt Paving Company, Philadelphia, and they will send you his name and address and also a copy of their useful and instructive "Good Roof Guide Book."

SURPASSES ITSELF.

Chas. H. Lilly Co.'s new seed catalog is just off the press and is now being mailed to their customers on the Pacific Coast.

The 1911 edition not only comes up to all expectations but surpasses itself in accurate descriptive matter and advice. The cover is very attractively lithographed from a hand-painted water color drawing and the inside pages contain hundreds of reproductions from actual photographs. It is a guide and a safe guide in every respect and a volume which should be consulted by everyone who plants seeds for business, profit or pleasure.

The catalog was compiled and printed by the Chas. H. Lilly Co., who are beginning their twenty-sixth year of successful seed selling in the West.

A SUGGESTION.

We wish to tell you of a remarkable business house that offers genuine advantages. We refer to the National Cloak & Suit Company of New York City, whose advertisement appears on page 165 of this issue. It will pay you both to read and answer this advertisement.

The "National," as this famous house is familiarly known, has customers in every town and county in every state in America. It has been in business nearly a quarter of a century, and in some ways, is one of the most remarkable business houses in the country.

It is remarkable first, because it pays all express charges on everything you buy, no matter whether ten cents' or ten dollars' worth. Now, the "National" sells by mail all kinds of Apparel for Women, Misses, Girls and Boys. Write for the free "National" Style Book, offered in the advertisement. It is very interesting, very beautiful, and it will save you money. You will be delighted with the treatment you receive, with the prices, and with the merchandise you receive from this grand old house.

So write for your copy of the "National" Style Book which, at our request, they are now holding personally for you.

HIGH-PRICED LAND.

One of the most attractive descriptive catalogues touching upon special crops is that issued by A. O. Gilbertson, grower of special crops at Mason City, Iowa. Onions and raspberries seem to be the principal features touched upon in the booklet, and the varieties handled by Mr. Gilbertson are certainly profit-bringers. The information he has to give is well worth writing for. He tells how to handle crops and high-priced land and how to create high-priced land.

FARM LEVEL IS ESSENTIAL.

The farmer who undertakes to level his land for irrigation, run irrigation ditches, canals and laterals; plan a drain, or establish a grade with the eye only to suggest, or some home-made makeshift to assist, invariably meets disappointment. The only way to attain successful results is to use a dependable telescope leveling instrument. If all of us were engineers and owned costly levels, these simple matters would be easy. Fortunately there are on the market simple, inexpensive levels, made purposely for the farmer; $15 will buy one, and so invested will bring great returns.

The Bostrom improved farm level advertised in this issue will meet the requirements for all kinds of irrigation work, drainage, either tile or open; terracing, ditching, road building, house foundation work, grading of all kinds, setting out orchards, running fences, getting angles and every sort of farm work requiring a level. Farmers, as a rule, have most of the common tools and implements for doing farm work, the level excepted. Now that this is available to up-to-date farms of the substantial farmers, this recent addition to the farm equipment may prove most helpful in performing many of these tasks that have heretofore been done by guess, and, therefore, unsatisfactory. Write nearest agent for particulars, mentioning that you saw this ad in Cultivator.

A PIONEER.

One of the oldest business houses on the coast is that of Barker Bros., furniture dealers of Los Angeles, established in that city more than thirty years ago, at which time it was a very modest concern in a town of 11,000 people. The town has increased to 319,000, and the increase in the business of the Barker Bros. has been in keeping with the growth of the city. They have one of the most complete lines of furniture of all grades from the most modest to the most fastidious, and have always believed in good furniture at popular prices.

THE EGG-MAKING MACHINE.

With eggs holding a good price on the market and yielding big profits, farmers are bending every effort to increase their production. In order to do this, special attention should be given to the egg-making elements of the poultry food.

To insure a bigger laying at this season of the year, cracked corn, ground bone, oyster and other shells should be fed liberally. In fact this is a necessity. You can furnish your poultry this food at lowest cost by using an "Enterprise" bone, shell and corn mill. This mill has truthfully been called the "Egg-Making Machine." With it you can make the finest egg material possible. The increased profits in a single year will more than cover its cost. May be used also for making bone meal fertilizer. A good all-round mill for farmers and poultrymen, for grinding dry bones, oyster and other shells, corn, roots, bark, grain, etc. Its weight is 60 pounds—capacity 1¼ bushels of corn per hour. The name "Enterprise" is on every mill.

Your name and address with 4 cents in stamps will bring you a copy of "The Enterprising Housekeeper"—200 recipes and helps in the kitchen. Address The Enterprise Manufacturing Company of Pa., Department 61, Philadelphia, Pa.

GOOD COFFEE MAKING.

In this issue we show an aluminum, sanitary coffee percolator which will enable you to make excellent coffee at one-half the price you now pay. It holds the coffee at the boiling point because it floats. It keeps the pot free from sediment, does away with eggs for clarifying and does not require a strainer. The price at which it is sold makes it possible for every household to possess this modern convenience.

STEEL POSTS.

The American Steel Post Company has been awarded the contract for their "Carbo" steel posts to be used for building the drift fence for the United States Bureau of Animal Industry, Washington, D. C., which also has a branch office in Los Angeles, Cal. This fence is being built under the detail specifications of the United States Forester at San Diego, and great care is being taken with respect to construction to make this fence serve the purposes of keeping cattle from ranging from the Mexican territory into the United States, thus prohibiting the bringing in of ticks and diseases.

The stretch now under construction south of San Diego runs along the boundary line from the oceean to the mountains.

HEIDER EVENERS A GREAT INVENTION.

Horse and man power are saved by Heider Eveners, made by the Heider Manufacturing Co., 152 Main St., Carroll, Ia. Thousands of them are now being used by farmers everywhere because of their utility and satisfactory results. These eveners are made for two, three, four, five or six horses. The four-horse plow eveners work four horses abreast on gang, sulky or disc plows—one horse in the furrow and three on land.

Most dealers handle this line, but if yours does not, you can get an illustrated booklet free by writing the Heider Manufacturing Co., 152 Main St., Carroll, Ia.

The Empire Cream Separotor Co., Ltd., of Portland, Oregon, who handle the "Easy Running Empire Cream Separator," that is known the world over for its light running, close skimming and simplicity, have taken on the Lauson Frost King Gasoline Engine. They did this after trying out several makes, as it proved to be the smoothest running, most economical on fuel, and most simple to operate, and the engines that have been placed with customers are giving excellent satisfaction. Their ad will appear in this paper referring both to their cream separator and to the Lauson Frost King Engine.

HOW THE WORLD SAYS GOOD-BY.

In different countries, just as the manner of greeting is varied, so is the habit of saying good-by. The Turk will solemnly cross his hands upon his breast and make a profound obeisance when he bids farewell. The genial Japanese will take his slippers off as you depart, and say with a smile: "You are going to leave my despicable house in your honorable journeyings. I regard thee."

In the Philippines the parting benediction is bestowed in rubbing a friend's face with one's hands. The German's Lebe wohl is not particularly sympathetic in its sound, but it is less embarrassing to those it speeds than the Hindu's performance, who, when you go from him, falls in the dust at your feet. The Fiji Islanders cross two red feathers. The natives of New Guinea exchange chocolate. The Burmese bend low and say "Hib, hib!" The "Auf wiedersehn" of the Austrians is the most feeling expression of farewell.

The Cuban would consider his good-by anything but a cordial one unless he was given a good cigar. The South Sea Islanders rattle each other's whale teeth necklaces. In the islands in the Straits of the Sound, the natives, at your going, will stoop down and clasp your foot. The Russian form of parting salutation is brief, consisting of the single word "Braschai," said to sound like a sneeze. The Otaheite Islander will twist the end of his departing guest's robe, and then solemnly shake his own hands three times.

LOOK FOR GOOD QUALITIES.

One generally finds what he is looking for.

If we look only for crooked trees in the timber, we will find plenty of them; but we will pass by many straight, beautiful trees and never notice them. So, too, if we look only for blemishes in the character of others, we will find them; but we may not notice the many good qualities that they may possess.

TO TAKE OUT PAINT.

Equal parts of ammonia and turpentine will take paint out of clothing, no matter how dry or hard it may be. Saturate the spot two or three times, then wash it out in soapsuds. A tablespoonful of oxalic acid dissolved in a pint of hot water will remove paint spots from the windows. Pour a little in a cup and apply to the spots with a swab, but be sure not to allow the acid to touch the hands. Brasses may be quickly cleaned with it. Great care must be taken in labeling the bottle and putting it out of the reach of children, as it is a deadly poison.

Thank God for the man who is cheerful
In spite of life's troubles, I say—
Who sings of a brighter tomorrow
Because of the clouds of today.
His life is a beautiful sermon,
And this is the lesson to me:
Meet trials with smiles, and they vanish;
Face cares with a song, and they flee.

Mayer SPECIAL MERIT SCHOOL SHOES

These shoes are built exceedingly strong. The leather is tough and the soles are selected from the best wear-resisting hides. They are the only school shoes made with two layers of leather over the tip.

"WEAR LIKE IRON"

MAYER SPECIAL MERIT SCHOOL SHOES

outlast average school shoes two to one and cost no more. They are good looking shoes, built to fit and comfortable to wear.

General Household Notes

GET TO WORK.

If the skies look dull to you,
Get to work;
If the atmosphere is blue,
Get to work.
Fostering your discontent
Will not pay the landlord's rent,
Will not gain for you a cent.
Get to work.

Brooding doesn't help your cause;
Get to work.
Nothing gained by picking flaws.
Get to work.
Weak are trampled by the strong?
You a victim of man's wrong?
"Stand the storm, it won't be long."
Get to work.

If success shall come, you must
Get to work.
There's no other way but just
Get to work.
It may yield not wealth or fame;
Much or little, just the same,
If you perish you'll die game.
Get to work. —Ex.

THE HAUGHTY MAUDE SUTTON.

"What do you think, girls? All my lessons are done for tomorrow, and I have nothing to fret about for twelve whole hours!" exclaimed Edith Carson, rushing into the room where three of her classmates were wrinkling their pretty brows over their algebra problems.

"Who helped you?" inquired Bess, without looking up.

"I helped myself," retorted Edith, indignantly. "The minute I got home I fell upon the lessons and hadn't a bit of trouble."

"Then, for pity's sake, take a look at my eighth. I've worked and worked and it won't come out even," said Nora, handing over a paper on which much erasing had been done.

"'Never ask assistance till you have exhausted your last bit of patience,'" quoted Edith, with a capital imitation of Mr. Stern's manner as he counseled his pupils in the schoolroom.

"Edith is as stuck-up over getting her lessons for once as Maude Sutton," said Bess. "I don't want to be wise if it makes people act like that girl. I hope you have not taken her for your model, Edie."

"I might do worse," said Edith, figuring away with a stubby pencil. "She knows everything and always gets the highest grades."

"Yes, I know that, but see how haughty it has made her. She seems to say, 'I am the youngest member of the class and the best scholar,' with every move she makes. I have tried and tried to be polite to her, but she barely speaks when we meet."

"She looks unhappy rather than haughty to me," remarked quiet Rose. "She is so pale and delicate looking that maybe she can't have fun like the rest of us."

"Unhappy! Nonsense!" said Nora, vigorously. "Her grandmother gives her everything she wants, and lets her do as she pleases. Look at her clothes! She wears better dresses to school than we have for best."

"Good clothes don't always stand for happiness. I think if papa and mamma were not with me I wouldn't care for anything, and maybe that is the way Maude feels too. I love grandma, but she don't take my parents' place," said Rose.

"I guess you are right," answered Nora, thoughtfully, "but I don't see why she is not at least pleasant to us. She ought to make an effort to be happy, or she will be miserable all her days. There! My work is done, too. Mamma said we might make taffy if we got through early, so come on to the kitchen."

* * * *

"Such an odd thing happened today, papa," said Bess Fuller, as she walked home with her father. "I picked up a letter on the street addressed to Joseph Smith, Indianapolis, Ind., and was walking toward the postoffice, intending to mail it, when Maude Sutton came along looking everywhere for something. I don't know what made me ask her, but I did if she had lost a letter, and she fairly snatched it out of my hand. She murmured something about losing it on her way to the train and then burst into tears. I can't think what I could have said or done to make her act like that, but she is always queer."

"Have you always been good friends?" inquired Mr. Fuller. Being a lawyer, he went at the root of the matter promptly.

"Why, yes. That is we never had any trouble. Maude has no friends, for she ignores all the girls. The letter had "I. P." on the corner and a long number—I mean something like five thousand and forty, though that is not the right one."

"It does seem odd that she should cry about a little thing like that," said Mr. Fuller. "It will be best if you don't mention this incident to your girl friends, Bess. Sometimes the wildest kind of reports start from little things like this, and it is always well to guard our lips closely. Be as kind as you can to the poor girl, for she may be too shy to make friends and is really longing for companionship."

"Her father and mother are dead—at least Rose said they were—and she lives with her grandmother. She has the nicest clothes of any girl in high school and gets the best grades. None of us can do as well in anything as she, but she never seems to work very hard."

The tribulations of examination drove everything else out of Bess's mind, and the letter was forgotten till one day she saw Maude coming from the southbound mail. "I wonder why she goes to the mail car so often to send her grandmother's letters," mused Bess, as the silent girl passed her with a slight bow. "They must be important."

Suddenly Maude turned and came back. "I beg your pardon, Miss Fuller, but would you go with me to your father's office?"

Bess was astonished beyond all measure at being addressed as Miss Fuller, and by the haughty Miss Sutton, but she managed to gasp out, "Certainly, whenever you want to go."

"I want to go right away if you think he is there. I have tried and tried to tell you how much I appreciate your not mentioning what you saw on my letter that day, but I just couldn't."

"I never said a word to anyone except papa, and he told me never to tell about it. He didn't say why, and I forgot about it till today."

"Didn't you know where it was going to?"

"Yes, to Indianapolis. I looked at the address to see if it belonged here, and noticed the city it was directed to."

By this time the two girls had

The California Cultivator leads in advertising and circulation.

reached Mr. Fuller's office, and Bess introduced Maude, who was making an effort to keep back the tears. "Come into the private office," said the gentleman, wondering what the young girl could want.

"You come too, Miss Fuller. I don't care if you hear, for you won't tell."

"It is about my father," began Maude, plunging into business at once. "Everybody here thinks he is dead, but he is in the state prison at Indianapolis. He was sent there two years ago, shortly after mamma died, and I have not seen him since. Grandma took me to live with her, and we came here where no one knew us, for she never wanted mamma to marry papa, and I don't dare mention him at home. She changed my name to Sutton, though it is really Smith, but as soon as I am old enough to earn my own living I will take my own again. Papa never stole the money they said he did, but we were too poor to hire a lawyer and grandma wouldn't do a thing for him."

"What is it you want me to do for you, you poor child?" said Mr. Fuller, as Maude paused to wipe away the tears. His own eyes were suspiciously wet, and Bess was sobbing in a big leather chair in the corner.

"I thought perhaps you could do something to get papa out. I haven't got any money now to pay you, but I'll soon be able to teach or do something, and I'll pay back every cent. I know papa is not well, though he does not say so, and I'm afraid he'll die in that horrid place. Grandma won't let me visit him, and he always says I must obey her, but I am so very unhappy."

"I will gladly do what I can, and you must not worry about paying me," said Mr. Fuller. "I have to be in Indianapolis next week on business and I'll call on your father if you give me his name and number. Perhaps we may think of some plan to help both of you. In the meantime, don't worry. Let Bess and the other girls cheer you up, so I may truly tell your father you are doing well. He worries about you, too, and you must take care of your health for his sake."

* * * *

"Was Mr. Smith a competent bookkeeper?" asked Mr. Fuller of the man who had been the prisoner's last employer.

"Very, and I wish we had never accused him of defaulting. You see, it seemed like a clear case, for he was caught passing the bills we had marked. I think we will do what we can to have him pardoned."

"But he won't accept a pardon," Mr. Fuller, looking the old man squarely in the face. "He says he has suffered unjustly and wants complete vindication. I think you know who robbed your safe and have never told."

It was a bold thing to do, but Joseph Smith had told him of suspicious things that happened in the office from time to time, and he determined to make at least one effort with the employer. To his surprise the rich man broke down and cried as if broken-hearted. "You are right," he said, feebly. "I do know, but I only found out last week. I hope, Mr. Fuller, that you may never know what it is to have a son rob you. Last week I discovered that my son was stealing from me, and that an innocent person was in prison for it. For his mother's sake I should like to keep it quiet, but if it must come out, justice shall be done."

"I will not ask that you name the thief," said Joseph Smith, when the matter was laid before him, "but you must make it plain that I have suffered unjustly. Mr. Fuller, I can never thank you for your efforts on my behalf. It seems like a dream that I am to see my little girl once more."

"You must come back to your old place at once," said his former employer. "In your native town the wrong was done, and there it must be righted. It is not to your old place either, for you will be made a member of the firm this very day. I can never thank you enough for allowing Edward to go free. It would break his invalid mother's heart to hear of it, but justice must be done. Can you ever forgive me?"

"Indeed I can," said Mr. Smith, looking pityingly at the heartbroken man before him. "You must not despair. We will see Edward a saved man yet."

* * * *

"Did you see papa?" inquired Maude, eagerly, as she and Bess saw Mr. Fuller coming from the train.

"Indeed I did, and he is well and happy," answered Mr. Fuller, shaking hands heartily. "He has a leave of absence and is coming to make you a visit."

Before half his sentence was uttered Mr. Smith had his daughter in his arms, and the two were laughing and crying in a way to astonish passers-by. Maude released her father at last and sobbed her thanks to Mr. Fuller, while Rose stood looking on with eyes and mouth wide open. "Am I dreaming?" she managed to ask at last.

"Not a bit of it," laughed her father. "We will all go up to our house for tea right away. Mr. Smith and I are almost starved."

"And to think this is the haughty Miss Sutton?" said Rose, as all the girls gathered around to congratulate a radiantly happy girl next day.

"You never called her haughty," said Nora, kissing Maude. "The rest of us did though. You said she was unhappy."

"You may say what you please, all of you," declared Maude. "Grandma and papa are good friends, and I am perfectly happy to think all my troubles have disappeared."

"Maude Sutton has disapeared," explained Bess, gravely. "Ladies, allow me to present my friend, Miss Smith. She has a very unusual name, but I hope you will not have to use the prefix 'haughty' to keep her in remembrance."

"Nor unhappy either," added Rose, and Maude thanked her with tears of joy in her eyes.—Classmate.

TO MAKE A GOOD CONSOMME.

To nearly five quarts of clear, cold water add two and a half pounds of lean beef, cut in small pieces, one fowl cut in pieces and the larger bones cracked and the meat also cut in pieces. Cover tightly and bring slowly to a boil. Watch carefully and skim off every particle of scum as it rises. Now add one slice of onion, one carrot, a bay leaf, a small bunch of sweet herbs, and a slice of turnip if it is not bitter. Let it simmer very gently for two hours, then add salt and pepper to taste; about one rounding teaspoon of salt and a third of the quantity of pepper will suit the taste of most persons. Cover again and let it just bubble for four hours longer. At the end of that time strain and set away to cool. Remove the fat and store in a cold place until wanted.

HEAR IT.

Ball: What is silence?

Hall: The college yell of the school of experience.—Harper's Bazar.

The Right Paint For This Spring

You can't afford to let your house stand exposed till oil drops in price. The way things look now, the buildings would be paint-hungry before that time comes.

Get the cost of 100 pounds "Dutch Boy Painter" White Lead, 4 gallons pure linseed oil, 1 gallon turpentine, 1 pint turpentine drier—this makes 8 gallons of pure white lead paint. Divide by 8 for the price per gallon and compare this with the price of any other paint you'd think of using.

You'll find that the best is the cheapest; also that, after all, the increase in the cost of "Dutch Boy Painter" White Lead made-to-order paint is trifling.

Write for our free "Helps No. 426
It answers all paint questions.

Dark comb	12½
Extracted white	8
Extracted dark	6½
Beeswax, lb	24@30

Scott, Magner & Miller say:

Arrivals of hay for the week have been 2700 tons, which is exactly the same as we received on the San Francisco market for the previous week.

At interior points we find a continuation of the recent demand, and this, no doubt, will continue while weather conditions remain as they are, and until there is a chance for the grass to show itself.

There has been a little better feeling in the export trade during the week, and there has been quite a lot of hay sent forward on export and coastwise orders. This trade has relieved the market this week considerably.

The demand for alfalfa hay recently has been better than was anticipated, and the market continues steady for what is being offered.

We quote the wholesale prices in round lots on today's market as follows, viz.:

Fancy wheat	13.00@13.50
No. 1 wheat or wh and oat	11.50@12.00
No. 2 wheat or wh and oat	10.00@11.00
Choice tame oat	11.50@12.00
Other tame oat	9.00@10.50
Wild oat	8.00@10.00
Stock hay	6.00@7.00
Alfalfa, ton	9.00@12.00
Straw	40@50

Grain.

Wheat, No. 1	1.42½@1.52½
Barley, fancy	1.16¼
Barley, good to choice	1.12½@1.15
Barley, poor to fair	1.07½@1.11¼
Oats, white	1.45@1.52½
Rye, new crop	1.50@1.60
Alfalfa seed	18@20
Mustard, brown	4½
Millet	2¾
Flaxseed	5@5¼
Broom corn seed, ton	23.50

Feed Stuff.

Alfalfa meal	17.00@18.00
Bran, ton	29.00@30.00

Feed cornmeal, ton	33.00@34.00
Cracked corn	33.00@34.00
Ground barley, ton	24.00@25.00
Rolled oats, ton	29.00@31.00
Middlings	34.00@36.50
Oil cake, ton	40.00@41.50
Cocoanut cake, ton	25.00@26.00
Mixed feed, ton	25.00@27.00
Shorts	29.00@31.00

Citrus Fruit Market

LOS ANGELES, Feb. 8, 1911.

The keeping quality of the fruit is disappointing. The spotting of the skin has caused lowering of its appearance, and now some of the fruit is going down as badly as it usually does during blossoming time. It is possible this is from the continued rains to a certain extent, but it is felt that it is more because of general soft condition. Good fruit is commanding a slightly better sale than last week.

The lemon market continues exceptionally strong, and all fruit that is offered is picked up at good prices.

Shipments.

Shipments of oranges to date since November 1, 1910: 7,462 cars; lemons, 1,189. Total citrus fruits, 8,651. To same date last season: 4,385 oranges, 1,067 lemons; total, 5,452.

NEW YORK, Monday, Feb. 6.—Twenty-six cars navels and four cars lemons sold. Market easier on navels, steady on lemons. Snowstorm raging.

QUERIES.

(Continued from Page 182.)

Orange Wine.

Can you give me recipe for making orange wine?—Subscriber, Ramona, San Diego county.

We cannot, and will ask our subscribers who have had experience to send in their formulas.

Borers.

Please tell me how to prevent borers from killing young trees. Would like to have the formula consisting of carbolic acid and other ingredients. —Subscriber, Vacaville.

The best way to prevent borers from getting into trees is to prevent sunburn which gives them opportunity for starting their work. Sunburn may be prevented by tree protectors, newspaper wraps, or any protection against the afternoon sun. When the injury to the trunk has been permitted use wash of one pound of coal tar to five pounds of quicklime, the coal tar being added while the lime is slaking. This should be applied during the month of April. The borers now in the trunks of the trees should be cut out or killed with slender wire. Another application which has been recommended is a good cheap wash consisting of a pound of paraffine, seven pounds of rosin and a half pint of flaxseed oil.

Fertilizing Alfalfa.

I have a small patch of alfalfa for green feed for chickens. Soil is very light and sandy. Will stable manure help it grow or is there a commercial fertilizer that would answer? How can I kill the grass which is infesting it?—Subscriber, Glendora.

Stable manure certainly would be beneficial to your alfalfa. It would carry some weed seed, but apparently you have a good supply of wild grasses infesting your patch already. We know of no better way of eradicating weeds than by plowing deeply and reseeding with alfalfa. Sometimes where Bermuda or other grasses are serious pests it is best to give the land over to clean culture of some other crops for a year or two until the pest is eradicated. Any good complete commercial fertilizer would help alfalfa, but unless the field is fairly free from weeds, it would not pay to apply it. 1000 pounds per acre should be sufficient.

Horsepower of Engine.

How can I figure out the horsepower of my gas engine?—Subscriber, Lincoln.

It is a physical impossibility to determine the horsepower of gas engine other than by "brake" system of actual test. The difference in engines with same diameter of piston head is so great as to make wide variations. We know of one engine which was sold for 15 horsepower. Under actual brake test it showed only 12. A thorough overhauling with installing of new valves on more scientific basis, enabled the engine to develop 23 horsepower under "brake" test.

To describe manner of taking this test with rules for figuring out is too extended for these columns and practically impossible for the novice to manipulate without expert advice. In a word, it consists of a friction belt or lever working on the flywheel of the engine, applying friction just sufficient to prevent any "cutting out." The friction pull on spring scales gives the data for determining the actual horsepower developed in the engine.

No matter if you are hidden in an obscure post, never content yourself with doing your second best, however unimportant the occasion.—General Phil Sherman.

16 CENT SEED SALE

10,000 KERNELS OF Selected FERTILE SEEDS for 16c

1500 Lettuce	1000 Celery
1000 Onion	100 Parsley
1000 Radish	1500 Rutabaga
100 Tomato	1000 Carrot
1500 Turnip	100 Melon

1200 Brilliant Flower Seeds, 50 sorts

Any one of these packages is worth the price we ask for the whole 10,000 kernels to start with. It is merely our way of letting you test our seed—proving to you how mighty good they are.

Send 16 cents in stamps to-day and we will send you this great collection of seeds by return mail. We'll also mail you absolutely free our great catalog for 1911—all postpaid.

EUCALYPTUS MARGINATA IN THE PRIMEVAL FOREST OF AUSTRALIA

THE JARRAH

We regret that Eucalyptus Marginata, commonly known as Jarrah, does not do well in California, for many admirable qualities obtain in it. In Australia it is the peer of all the best of the timbers. We refer readers to article by Mr. Blackburne on page 216 of this issue.

The Jarrah grows in Australia all over the Southwestern division and almost invariably intermixed with red gum (Eucalyptus calophylla) and in some places with blackbutt (Eucalyptus patens) as well, the latter always in the hollows and richer portions of the district. In some parts of the karri (Eucalyptus diversicolor) country Jarrah appears to mix with the former, except in places where the karri takes possession of the ground to the exclusion of all others.

Its resistance to white ants is remarkable and houses built of the wood when thoroughly seasoned, are almost indestructible, and have been known to exist in perfect preservation for nearly 100 years. It gets extremely hard with age and then becomes almost unworkable, even strong nails can not be driven into it and when struck the wood rings like a bell. Altogether. it is a remarkable timber and is highly suitable for outside works. Should any decay or destruction have occurred in the timber after having been years in use, it will always be found that this is confined to the sap-wood.

The weight of the wood when newly cut, is little over 70 pounds per cubic foot, which is reduced to 60 pounds when thoroughly seasoned. It is red in color, polishes well and is comparatively easily worked.

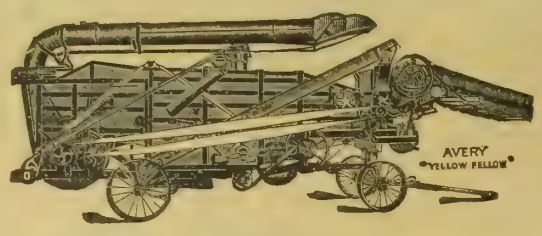
There are instances of railway sleepers which were laid down eighteen years ago and still appear as sound as ever.

Unfortunately, sufficient attention is not always paid to the seasoning of timber and hence disappointment sometimes ensues. When used as flooring boards, it should especially be thoroughly seasoned, otherwise there will be much warping, buckling and an unsatisfactory floor altogether; if seasoned before being laid, however, a better floor could not exist.

The Avery "Yellow Fellow" Grain Separator

It's the Machine to *Make You Money* —Mr. Thresherman

Built to last—not one of the kind that is worn out as soon or before you get it paid for. Better braced frame, heavier shafting—tank steel windstacker, not sheet iron—tool steel teeth, not machine steel—these are samples of the stronger—longer lasting—construction of the Avery.



THE AVERY "YELLOW FELLOW"
The Thresherman's Money Maker and the Farmer's Grain Saver

No Tinkering

A Thresherman bought a new Separator, used it only three years, and last season bought a new Avery. He gave as one reason—"We know there will be no tinkering teeth or other delay with the Avery."

"The whole season through without a single breakdown" is the story that Avery Threshermen tell us time after time. That's one of the reasons they are big money makers for their owners.

Threshes Fast

"Yellow Fellows" are "record run" makers. No flimsy contraptions in the feeding devices or on the racks to slow everything down. Larger runs and more profits are the *rule* with owners of Avery "Yellow Fellows."

It's the Machine to *Save Your Grain* —Mr. Grain Growing Farmer

In order to show you just what an Avery Separator will do in saving your grain, we have made a large number of canvas tests. These tests show an average saving of 99.92 per cent. Think of it—only 1-13 of 1 per cent wastage. *Almost nothing.* The way to make sure that your grain goes into the wagon and not into the straw is to get it threshed with an Avery "Yellow Fellow" Separator. Insist upon its being a Grain Saving Avery that threshes your grain.

And It Does Extra Good Cleaning

A farmer wrote us "Never had such a clean job done before." An elevator owner says, "The Avery 'Yellow Fellow' sends me the cleanest grain that I ever received." Study the construction of an Avery and you will easily see why it's a grain saver and a grain cleaner.

Does Quick Work and Gets Away

"No tinkering around" is what one farmer wrote about the work of an Avery "Yellow Fellow" and that tells the whole story. Does clean work and quick work and isn't always breaking down on your job. Cleans your job up right and does it quick.

Furthermore—Avery Separators Are Backed Up By the Strongest Warranties Against Breakage and on Separating and Cleaning the Grain of Any Threshing Machines Made

Find Out All About the Avery "Yellow Fellow" Separator

If you are a thresherman you ought to investigate it fully because it's a Money Maker for you. If you are a Grain Growing Farmer you ought to find out all about how it will Clean and Save your Grain.

Write at once for our large free catalog showing the Avery "Yellow Fellow" in natural colors, and telling all about how it is built. Address your letter or postal as follows:

New Method of Grafting Fig and Olive Trees

Interesting Article by Mr. George C. Roeding, of Fresno, who Originated the Method. Scions Should be Cut at Once and the Grafting Done Very Soon. Undesirable Orchards are Made More Profitable.

Time for grafting is here. Methods of grafting there are many. Those who have grafted the apple with the cleft in which a couple of scions are wedged on either side have found it extremely simple and almost certain of growth. The fig, the olive, and some other trees require other methods. We have asked Mr. Roeding to give of the latest methods for The Cultivator. He writes the following which he gave in part in The Cultivator once before, but it is now revised and added to by him, and two of the photos and engravings were made from grafted specimens prepared especially for this issue.—Ed.

* * *

The successful production of the Calimyrna fig and its undoubted future as one of the great industries of this state has led many owners of fig orchards to make inquiries as to whether or not their old trees of the ordinary varieties could be grafted over into the new fig. The answer to such questions is that there is no necessity of digging up old trees, as they can be readily worked over into either the Calimyrna or Capri fig, without in either case affecting the quality of the fruit produced.

The writer has been experimenting with the grafting of the fig for a number of years, and has finally adopted a method, which may be said to be entirely new, and is to be recommended over the ordinary wedge or cleft graft, which, to say the least, is crude and unworkmanlike, and can not even with the greatest care be done with any degree of satisfaction, particularly on an old tree with large branches, where the great pressure on the scion often destroys the cambium layer and kills the scion. Another objection to the method of splitting is that the split made by the chisel has a tendency to split wider open when the warm weather sets in, and it takes a long time for the wound to heal over.

Best Size of Stock.

In grafting over orchard trees the branches to be grafted should be cut off to within 18 to 24 inches from the point of divergence from the body of the tree, allowing at least two branches to remain, one of which should be on the southwest if possible, so that the grafts will be shaded from the afternoon sun.

The object in leaving the branches is for the purpose of having an outlet for the sap, for the removal of the entire top of the tree is dangerous. In the coast counties fig trees, and other trees as well, can have their entire tops removed, and still withstand the shock, the scions taking readily, if properly inserted, but in the interior valleys, where the atmosphere is dry and warm, to remove the entire top of a fig tree close to the main body would result in the loss of the tree, a fact which has been fully demonstrated by the writer by actual experience. The two branches which have been allowed to remain can be sawed off entirely the following season, or they can be in turn grafted, if the scions of the year before have not taken well, or if you have not sufficient branches from your preceding season's grafting to form a good head on the tree.

The Scion.

After having sawed off the branches the stumps or subjects to be worked on should have the tops neatly smoothed over with a sharp knife so as to have a clean, smooth surface, particularly along the edge. From two to four scions should be placed in each stock, the number of course being regulated by the size of the stump. Cut out a V-shaped piece of bark; the distance from the top of the stock to the point of the V should be from 1 to 1¼ inch.

In recent years, I have made a decided improvement in fitting the scions to the stock. The scion is placed against the stock. The outline of the scion is cut into the stock so that when the bark is removed, the scion fits closely into the groove made for it. (See Fig. 1.)

Select a scion of the proper size, making a sloping cut along the lower end, as long or somewhat longer than the incision on the stock. The scions should be cut the same as for a whip graft, except that the cut is all on one side and should have a little more bevel and the second cut for the tongue of the whip graft should be omitted. The scions should never be smaller than an ordinary lead pencil; as a rule scions from two-year-old wood, as they have very little pith, with a diameter of 5-16 to ½ inch will be found to give the best results.

The scion should be of such a size that it fits snugly into the opening in the stock, so that the bark on both sides of the scion touches the bark of the stock. After the scions are placed, wrap tightly with five or six-ply cotton twine, so as to hold them in place, and cover the wounds as well as the stub with liquid grafting wax. Also be careful to wax the top of the scion to prevent drying out. Never use wax cloth for wrapping, or if you do, be careful to remove it early in the summer before the warm weather sets in or the bark, when the grafts are set, will be smothered and the grafts will die. After the scions have become well united, which takes from two to three months, the strings can be cut.

The writer prefers this method of grafting to all others and has had no difficulty in making fully 90 per cent of the scions grow, many of them making a growth of 5 to 7 feet in a single season. This method of grafting cannot be practiced until the sap begins to flow, and from the latter part of February to the 1st of April has been found to be the best time. The scions should never be more than 4 inches long.

Figure 1.—Fig stump with scion exposed, showing method of cutting, also opening cut in stump for scion. Two scions set in other stump and tied ready for waxing. At base are fig cuttings showing proper character of grafting wood, about ½ to ⅝ inch in diameter.

Figure 2.—An olive stump showing method lifting bark for inserting scion with scion cut for insertion. Other stump showing three scions set and tied ready for wax. Note twig buds on scions. These should be obtained if possible. Scions ¼ to ⅜ inch in diameter.

Wax.

The grafting wax should be melted in a pot and put on hot, using a small paint brush or a brush made out of short pieces of hay rope tied to a small stick answers the purpose just as well. The best results have been secured by using a wax made of one pound beeswax, three pounds resin and three ounces of raw linseed oil by weight. Place the beeswax and resin in a kettle and cook same until thoroughly dissolved, then add the oil and allow the ingredients to cook slowly for ten or fifteen minutes longer. Remove from the fire and as soon as the wax has cooled some pour a small quantity into a bucket of lukewarm water. Grease the hands and take the congealed mass and knead and pull it until it becomes very tough; wrap in oiled paper and it is ready for use. By preparing the wax beforehand the ingredients are mixed in proper proportions, which is not easy to do when you have a large amount of work to do in the field. This wax is also far superior to wax which has not been pulled.

(Continued on Page 198.)

LARGEST CITRUS NURSERIES IN THE WORLD

Parties contemplating the planting of citrus groves this coming spring will do well to send for our prices soon, as there will evidently be a shortage of strictly first class stock. Write today for particulars, or, better still, pay us a visit so that we may be able to show you just what we have.

THE SCALE PROBLEM.

By G. W. Waterbury, Corona.

That we are breaking even in our warfare with the scale I doubt. In making this assertion I cannot but express my appreciation of the high standard now extant in the desperate efforts of the scale fighters to subdue the microscopic insects that seemingly are not alone bent upon self preservation, but upon actual conquest. That the well-organized system for scale destruction was never upon such a high standard as at the present time we know; that the number of trees to be fumigated and refumigated next year will be larger than ever before we know to be an actuality that cannot be ignored. With financial losses running over half a million dollars annually for Southern California for scale fighting and no end in sight; with the bulk of our orange shipments this year bringing less than $2.50 per box and a magazine publishing anti-tariff write-ups on information furnished by the New York importers, what then will be the outcome? Clearly then, the one hope is to cheapen operating expenses. Without doubt our largest expense is fumigation.

In my trip through the citrus sections of the coast last fall I found in too many cases, more especially in San Diego county, a tendency to let the natural parasites handle the scale problem, unaided by man. This is a failure because the scale was far more willing to work overtime than the parasites. Seemingly the scrutellista spent much time in sleep. I am equally sure the scale never indulged in such foolish pastimes.

The agricultural experiment station of our State University has ever been willing to do what it could in the work of scale eradication and Mr. C. W. Woodworth was working on the question twelve years ago. The national government has likewise been interested and Entomologist R. S. Woglum spent two years investigating the question of fumigation. He gave us a dosage chart, suggested sodium cyanide and said that the scales could be killed "if conditions were right." Seemingly conditions are never right —except for the scale.

That the black scale can be controlled within reasonable bounds we know; that the red can be handled with a considerable degree of success on the orange we also know. But that the red and purple scales on the lemon are more than a match for us I am now led to believe. Before the battle turns in our favor there must be variations in our present system and one of two things must occur: either we must declare embargo districts after fumigating a solid block of groves, or a more powerful, more deadly form of gas must be found that will do the work.

With the embargo district there must be a strict set of rules that will allow no variation. Every box must be fumigated before going into that section, as well as picker's bags and clippers; probably different clothes should be furnished when the men come from infected districts. There is some expense to all this, but it will fade into insignificance compared to that annual toll of 40 cents per tree. As soon as a tree shows fruit with live scale on it, it should be flagged and fumigated. The picking foreman would then become the real inspector in the lemon districts that are gone over every month for the fruit.

Should a more deadly gas be found that will solve the problem, it will win the battle for the orchardists, for the whole fight is over that three to five per cent of live scale that remains uninjured by our present form of cyanide. And the rapidity with which that three to five per cent spreads and compounds itself numerically is little short of marvelous. If the scrutellista or various vedalias or coccophoctonus would work half as lively we could well afford to house them in mansions of gold, with special service of silver plate to serve scales on.

In Corona 1700 acres were fumigated during the past year, according to Deputy Commissioner Tuthill, and probably all of this will have to be gone over during 1911 and another $50,000 taken out of the pockets of the orchardists. In Redlands $100,000 was spent and the scale is as vigorous now as a year or so ago. There are some lemon groves in Corona that have been fumigated twice during the last year and the scale not killed. One grove has had three fumigations for red scale in 15 months and another one is now due. One thrifty grove was fumigated last spring and now shows 300 trees infected badly. In this last case it may be stated that this was partly due to placing too much credence in Woglum's chart and his conversion of potassium to sodium bases for generating gas. It was found without exception that 60 per cent of sodium was not equal to 100 per cent of potassium cyanide and a change was made to 75 per cent, with better results.

H. H. Holmes, once horticultural commissioner of Riverside county, used to state that by thorough work by the fumigating companies, our lemon trees should not be fumigated oftener than once in two years, possibly once in three. Today he is less optimistic, and believes it is now a question of once every year.

Mr. Strong, at one time commissioner of Los Angeles county, was convinced that the red scale could be killed but stated all branches should be up from the ground, all fruit and brush raked from under the trees and climatic conditions just right. During the past twelve months all these conditions have been fulfilled at different times and yet the second inspection some sixty days later showed live scale on the leaves and fruit. The commissioners are no longer sanguine about complete extinction; to hold the scale in check with annual doses of cyanide is their present endeavor.

On my own grove the fumigation was very carefully done last May, when Deputy Commissioner Tuthill, with Mr. Stacy, the local fumigator, carefully stepped and estimated the dosage per tree during the day time and the extreme limit of Woglum's chart was used in the work at night. The work was carefully done and all conditions were favorable at the time. A second inspection sixty days later showed some 18 trees with live scale and now there are enough red scale to warrant another fumigation before May unless I wish to take chances of

the scale getting on the fruit, causing it to grade lower.

The cases I have mentioned were not due to careless fumigation; the work was of the best. There were new tents, plenty of gas was used and the tents were measured by up and down figures and the circumference taken with a tape line, thus eliminating the guess work once far more prevalent. Probably in no infected section of the state is the work of fumigation more thoroughly done than in the lemon district of Corona, for we realize that unless the leaves are kept healthy and full of chlorophyll proper nutrition cannot take place and if our lemons go out spotted there will be lowering of the high standard now maintained. By fumigation, constant fumigation, I admit it can, in the majority of cases, be kept down, but how about that $35 per acre annually and the $1,500,000 annual toll for scale fighting in California? With the constant increase in heavy orange plantings and the New York importers, free use of hack writers to attack the lemon tariff where will the citrus growers be unless operating expenses can be curtailed and chief of such expenses, as I said before, is the annual financial outlay for fighting scale.

ADVERTISING FRUITS.

Answering the complaint that Florida oranges are not the favorites they once were, the Fruitman's Guide says:

Lots of reasons, more or less plausible, have been presented in the way of explanation. The favorite one seems to be the abnormal lateness of the Florida harvest and the abnormal earliness of the California product. We do not recollect, however, running across the theory that the real root of the trouble lies in the consumer and not in the fruit.

Once upon a time, as the fairy stories have it, the country swore by the Florida orange. Its uncomely looks were held as a sure sign of a hidden sweetness. Its very rustiness and roughness betokened its aristocratic lineage and proudly proclaimed that its virtues were far above and beyond mere skin-deep beauty. People wanted oranges to eat, not to admire. They aimed to please their palates, not their eyes.

Times have changed, though, and people with them. The consumer buys by the eye. A large percentage of the fruit you will see on a swell dinner table is there to adorn, not to be eaten. It is a pity, but pity 'tis, 'tis true.

For all that, Florida need not lose hope. It is merely a question of a campaign of education. The public needs to be reintroduced to the unsurpassed excellencies of the Florida product. There is only one way to do this, and that is to advertise. If the different shippers and marketing agencies of Florida, exchange and the independents alike, would sink their differences and join in the common cause, much could be done. An arrangement whereby so many cents per box on every box shipped out of the state should be pulled back to swell an advertising fund, is the suggestion of a broad plan, the details of which could be worked out in plenty of time for next season.

California has done much along this line to her great profit. She has, and righteously so, worked the newspapers to a fare-you-well. The excellencies and beauty of her navel oranges and the advantage of their seedlessness, have been sung from coast to coast in type, leaded and solid, display and pure reading matter, preferred position, three stars, and every device known to topography. She neglects no device in the advertising bag of tricks, and returns are such that the more she advertises the more she wants to.

Florida must get next to the consumer. It must tell him all over again what his fathers knew so well. It must re-educate him to the glories of lusciousness hidden behind that not-over-attractive skin. Teach him the proper way to eat an orange, suggest to him new methods and dishes in which the orange may be employed. Teach him that an orange with seeds has compensations to back up its claims against an orange without seeds. In fact and in short, plug for Florida just as California first, last and all the time plugs for California. In the lump it may be a costly campaign, but the burden divided up among so many shippers will be individually a light one.

There should be no difficulty in doing for the industry what Kimball C. Atwood has done for himself individually in the matter of the Atwood grape fruit. It is merely a question of getting together on a plan that will provide the sinews of war and. when provided, put it in the heads of the right man or men to do the best they can with the funds gotten together.

Just recall for a moment what advertising did for the California prune; what it has done and is doing right now for the Hawaiian pineapple. It will not be so difficult a job as some people think to reawaken the American people to the merits of the Florida orange and recreate the appetite for this delicious fruit—an appetite which during the past few years, seems to have waned most woefully.

But, and this is a great big "but," all the advertising in the world will not carry the story home if at the very outset of the season the public taste is nauseated, disgusted, or set on edge by shipments of immature and acid fruit that ought to be kept at home. Advertise to the public that Florida has an orange that cannot be surpassed, and back up your advertisements by giving them such an orange. —Fruitman's Guide.

MEALY BUG PARASITES.

Commissioner Beers of Santa Barbara county reports:

"The clean citrus fruits being received from local orchards evidence the effective work of the parasites against scale troubles. We are enabled to gradually extend the number of colonies of the parasites against the Mealy bug and are frequently receiving additional material from the state insectary to keep our stock in the local hatching cage thrifty and abundant. We hope to finally secure a mastery over this dreaded pest."

LEMON SIZES.

The sizes of lemons packed for shipment differ from those used in packing the orange for shipment. The sizes are 210, 240, 250, 275, 288, 300, 360 and 420. Occasionally larger and smaller sizes are packed, should the market warrant their shipment. Of the sizes named, the 300 and 360 are recognized by the trade as regular sizes, and all others known as off sizes.

Soils breathe. If left open and well tilled, the breathing is facilitated, and great benefit is secured through aeration and encouragement of beneficial bacteria.

The Orland irrigation project is now ready to irrigate 4000 acres of land.

You Need a

SOIL SAMPLER

—Prof. King introduced this valuable tool before the Los Angeles Citrus Convention. Spring is coming, your soil will need attention. Its condition should be known throughout the orchard. With the Soil Sampler, in a few minutes and a little effort, you can get solid cores of soil to a depth of four feet, enabling you to see condition of each stratum. Don't delay, let me tell you about it. Write Fruit Growers Supply Co., or C. D. FILSTEAD, Mgr., RIVERSIDE, CALIF.

Genuine Florida SOUR ORANGE SEED-BED TREES

Extra fine one year stock, the best to be had; be sure you are getting the genuine article. If you will send your orders in now, we are prepared to fill them, be they large or small; but order early, as the supply is limited.

3,000 fine large two year Valencias, get our prices.

Deciduous Bush-Tree Fruits

GRAFTING FIGS AND OLIVES.

(Continued from Page 195.)

Walnuts, pears, olives, in fact, almost any variety of deciduous tree, can be grafted by the method described, with far less work and much better results than with the clumsy and crude cleft graft, and a branch 12 to 14 inches in diameter can be as readily worked over as one 4 inches in diameter.

Olive Grafting.

In olive grafting, the method followed is to make an incision from the top of the stump down, just as would be done in setting a bud, and slip the scion into this incision. In following this method the wedge should extend further up on the scion, and should not be as abrupt as the cut on the scions for either figs or walnut grafting.

The best time to cut walnut, fig and olive scions is in February.

In selecting olive scions, as far as possible try and have the little twig buds on each scion, as these very rarely fail to start out, while the ordinary buds do. When this occurs the scion will die altogether in very hot climates or they will remain dormant until the following spring before starting. (See Fig. 2.)

Walnut and fig scions should never be less than three-eights of an inch in diameter, and always avoid very pithy wood. Olive scions should be not less than one-quarter inch in diameter.

The accompanying illustrations tend to make the descriptions very clear. The V-shaped or perhaps more correctly a U-shaped cut in the bark of the fig stock carried down to the alburnum or sap wood and the scion with its proper oblique cut, even and smooth, so that it plants itself evenly on the bared sap wood and is held firmly against it by the wrapping of cotton twine.

CALIFORNIA CHERRIES.

By J. W. Mills.

Cherries are one of the most profitable crops grown in the state when proper selection of soil and climate is made. Like other fruits, that grown in early sections brings the highest prices, first shipments from the Vacaville, Marysville and Newcastle sections often approach the $3,000 a car mark. About the time the cherry crop is cleaned up in these early sections, the main crop of the state is ready for shipment. This comes from counties bordering San Francisco Bay. The home market is soon stocked, when carload lots are daily sent to market in cherryless belts and the Eastern states. Those sections producing early cherries usually pay less for the fruit than their own brought.

WHITE ADRIATIC GRAFTED WITH CALIMYRNA FIG SCION

Some of the cherry growers in the bay section have what can rightfully be called gilt-edged fruit farms. Orange growers of the south, even those having the choicest groves, have a knotty problem compared with them. The orange grower has his scale insects to fight, monthly irrigations to attend to, and not the least perplexing task is keeping up proper fertility of the soil. Frost problems are always on the minds of the great majority of orange growers. One crop of oranges is scarcely off, in the most favorable cases, before another is coming on, and in many cases two crops are on the trees at the same time. Eternal vigilance is the price of an orange crop, and, of course, it is worth it; but, comparing it with a cherry crop, note the difference. Within four months from the time of blooming, the entire crop is matured and a thing of the past. Irrigation is seldom practiced, and pruning and trimming up the orchard for the coming season can be done immediately after harvest,

146 East St., San Jose, Cal

The Turlock Irrigation District's high line canal work is being pushed, one contractor arriving last week with 80 mules.

leaving the balance of the year, till plowing time, for the grower to devote to other things. Those growers who devote their land exclusively to cherries have from June till late in the winter to follow other occupations. We know a grower who has a cherry orchard big enough to insure a handsome income, and when harvest time is past he locks up his house, and he and his family travel for several months.

This is what would truly be called gentleman farming, but where one man can do it there are several thousand who cannot. Besides, cherry growing is not all velvet, for it entails many difficulties some seasons, and when harvest time comes the cherry grower has to get a hustle on that a hundred years of orange growing would never suggest. Oranges will wait a few days, or weeks, or months, after they are ripe, but time, tide and cherries wait for no man. A moderate rain, followed by cool weather, will crack almost the entire crop. San Jose scale is a pest that requires watching, but compared with any of the citrus scales it is a very simple problem.

There have been many cherry failures, due almost invariably to unwise selection of soil or location. Cherries require a deep, rich, well drained but moist soil, but if it is subject to spring overflows there is danger of losing the trees. We have in mind a small orchard of Black Tartarians that was planted on deep black loam of the Feather river bottom, and in the third year they were perhaps the most magnificent trees of their age to be found anywhere in the state. When in bloom, at four years of age, high water from the spring rains killed every tree.

There are many nooks and corners along mountain streams in all parts of the state where cherries grow to perfection. Some of the finest cherries I have ever seen came from the San Bernardino mountains, above Mentone.

SURGERY FOR OLD APPLE TREES.

Do you have old apple trees on the place, with badly decayed trunks, and main branches which are starting to rot? If so, economy dictates that you do one of two things. If the trees are of a desirable variety and have been bearing well for you, you should do a little tree surgery. Otherwise the trees had better be cut down and the ground be put into some paying crop. Tree surgery is quite simple. All that is needed is several good, sharp chisels of various sizes and shapes, Portland cement, crushed rock, and corrosive sublimate solution (one part of corrosive sublimate in 1000 parts of water). The first thing to be done is to thoroughly cut out with the chisels all decayed wood. This done, the wound is washed out carefully with the corrosive sublimate solution. Then the hole is filled up with cement; cement alone if the hole is a small one, or cement and rock for economy's sake if the hole is a large one. A good, workmanlike job of putting in the cement should be done, and the outer surface of the cement should come out flush with the healthy wood. This simple treatment will stop decay and often preserve almost indefinitely valuable apple trees. Of course more treatment than this is necessary to completely rejuvenate an old orchard, but this, together with pruning, manuring and possibly tillage, will give back to many an old orchard its lost youth.—Wallace's Farmer.

SPRAY FOR WALNUT BLIGHT.

We note in Horticultural Commissioner Beers' report that Santa Barbara county is to prove out the Wylie walnut blight patent. Prof. Beers says:

"A definite movement is being made towards systematic spraying for the walnut blight, to demonstrate whether or not the solution discovered and patented by Mr. Wylie will prove as effective in other portions of the walnut sections as in his own orchard. Some extensive tracts will be sprayed, while very many have signified their purpose to try the same on small parts of their trees. The only hope seems to be that it prove efficacious."

We hope the hope will be realized, but many walnut growers declare only disappointment will result. It is most wise for the county to prove out the treatment before the growers make extensive trials.

WHITE ADRIATIC WITH SUMMER GROWTH OF GRAFTS

POTASH PRODUCES PEACHES.

Peach trees like potash. A tree growing in the rear of the kitchen got the soap-suds for many years. It made twice the growth of the peach trees in the orchard, although these grew in naturally better soil and had good cultivation and fertilization. The soap-sud tree never had an "off peach year."—Guy E. Mitchell.

It is useless to try to grow a good crop of apples unless plans are made to harvest the crop quickly and economically—and just here is where some fruit growers have lost a great deal of money. Their business methods were faulty, and they could not care for a crop after it was grown. If buyers could be secured to take the crop on the trees, all well and good; if not, then great loss followed.

Hanford, Kings county, reports the most extensive plantings of apricots in some years. Tiltons and Royals are the favorites.

Garden and Field Crops

SWEET POTATO CULTURE.

By R. H. Forbes, University of Arizona

Sweet potatoes and yams, being of tropical origin, are favored by a long, hot growing season.

Growing Slips for Planting.

Sweet potatoes are best propagated by means of slips or sprouts started in hotbeds or coldframes before danger of frost is over. In Southern Arizona we have found fire hotbeds most satisfactory, temperature in them being under better control than in the case of manure or coldframes. A very good sweet potato hotbed at little cost may be constructed as follows: A frame of rough boards seven feet wide, twenty feet long and fourteen inches deep is laid down over two flues made by digging two trenches one foot deep and about two feet wide, lengthwise of the bed. These trenches are covered with plank or iron roofing, and equipped with a fire pit at one end and short smokestack at the other.

Four inches of soil is filled into this bed and sweet potatoes placed upon it in a layer which is then covered with two or three inches more of good soil. Large potatoes may be split and laid flat side down. The whole bed is then covered with muslin, operating on a roller by which to cover and uncover the bed. Thus prepared, the bed may easily be kept at a temperature of 60 to 70 degrees F. by smouldering mesquite fires in the fire boxes. The potatoes, kept moist at this temperature, sprout promptly and will be ready to transplant in about six weeks. A bed of the size mentioned will receive five to seven bushels of seed roots which will make slips enough to plant an acre or more of potatoes. In Southern Arizona the seed potatoes should be bedded about February first in order to have slips ready for planting in March, when danger from frost is over.

The Soil and Its Preparation.

Light, sandy soils produce smooth potatoes; while heavy soils produce crooked, knotty tubers by reason of the physical resistance to developing roots offered by such soils.

Sweet potatoes are best grown in ridges about four feet apart from center to center, with irrigating furrows between. The field is first irrigated. At four foot intervals double furrows are then broken out, right and left, and a layer of manure placed in the bottom. The fertilized furrows are then plowed in, and ridges thrown up over them with the plow, leaving dead furrows for irrigating between. The rough ridges may finally be smoothed by lightly harrowing or planking them lengthwise; but they should be left high in order that the potatoes may have an abundance of loose soil in which to develop.

Transplanting.

Along the fertilized ridges thus prepared, slips from the hotbed are then firmly pressed into the soil at intervals of about one and a half feet, using a little water to insure success in transplanting. Only well-rooted slips should be used. An immediate irrigation in the furrows between ridges will then favor a high percentage of growing plants. Some varieties, as White Vineless, give a high percentage of loss in transplanting. It is therefore well, when possible, to plant late in the day or shelter from the sun by such covering as may be available.

Irrigation and Cultivation.

Frequent irrigations (two or three times a month at Yuma, Arizona, from April to September) are essential to a good yield of sweet potatoes, although once well established, they will withstand considerable drought. Until the vines prevent, the furrows should be cultivated after each irrigation to keep down weeds.

Varieties.

Under Southwestern conditions different varieties vary widely in quantity and productiveness. White Vineless, Yellow Jersey, Red Jersey, Large White, Mammoth Red and Georgia Yam have all been tried in the Yuma garden. The White Vineless is a good market potato, sweet and juicy, but very uncertain in transplanting, a large number of missed hills always occurring. As its name implies, this variety makes but a limited growth of runners. The Yellow Jersey transplants and yields well, producing a desirable crop of smooth, yellow tubers. The Red Jersey thus far produces poorly; while the Mammoth Red is of inferior quality. The Large White and the Georgia Yam are juicy and sweet, and produce heavily. Following are the results of a test of varieties made at Yuma in 1910. The yields are calculated to perfect stands of plants in the field: Red Jersey—8,090 pounds per acre; dry and sweet when baked. Yellow Jersey—24,830 pounds per acre; dry and sweet when baked. Mammoth Red—34,170 pounds per acre; moist and sweet when baked. Large White—43,290 pounds per acre; moist and very sweet when baked. White Vineless—25,000 pounds per acre (estimated); moist and very sweet when baked. Georgia Yam—53,310 pounds per acre; moist and very sweet when baked.

Taking yield, quality and hardiness into consideration, Yellow Jersey and Georgia Yam are probably the best of these six kinds. In this connection it is well to remember that Southern people usually choose sweet, juicy varieties, such as Georgia Yam, while Northerners prefer small, dry varieties, of which Yellow Jersey is one.

Harvesting and Marketing.

Sweet potatoes are often dug early in the season, on account of high prices; but are not then so sweet as later, when mature. The yield increases steadily until frost, at which time it is customary to cut the vines, in the belief that otherwise the quality will deteriorate.

HAPPINESS.

If thou workest at that which is before thee, following right reason seriously, vigorously, calmly, without allowing anything else to distract thee, but keeping thy divine part pure, if thou shouldst be bound to give it back immediately; if thou holdest to this, expecting nothing, fearing nothing, but satisfied with thy present activity according to nature, and with heroic truth in every word and sound which thou utterest, thou wilt live happy, and there is no man who is able to prevent this.—Marcus Aurelius.

THE CARNATION.

An excerpt of a paper read by W. T. Bell of Franklin, Pa., before the American Carnation Society.

Early History of the Carnation.

The Carnation, or, to express the name in strictly botanical terms, Dianthus caryophyllus, is, according to London, a native of southern Europe, and has been found growing naturally, in England. The generic name, Dianthus, is compounded of two Greek words, meaning the flower of the gods, which has led certain writers to call it the Divine Flower, a name that might well be exchanged for one more simple and comprehensible. The specific name, carophyllus, has reference to the clove-like fragrance of the flowers; while the common name, carnation, has for its base the Latin word "carnis," meaning flesh, in allusion to the pink or flesh color of the flowers in their wild state.

There are many different species in the genus Dianthus, including the familiar Sweet William; but the one that most nearly resembles the carnation in apearance is the pink, with its several varieties.

Where it grows naturally, the carnation has single flowers, about one inch in diameter, having but five petals; but variation, selection, and cultivation have so changed its character that flowers four inches in diameter are now produced, having a very great number of petals.

The ordinary garden carnation is a hardy perennial that blooms but once a year; the florist's carnation of today is undoubtedly the result of changes that have taken place in its habits, through selecting and cultivating the most promising plants produced by natural variation.

The development and improvement of the carnation have taken place within a comparatively recent time, both as regards the size, color and quality of its flowers and the number of desirable varieties. Thirty or forty years since, the florist was confined mainly to such kinds as Edwardsii, DeGrauw, La Purite, Miss Jolliff and Astoria.

Buttercup, one of the best of the earlier yellows, although like most of the later kinds of that color, decidedly bizarre, came later, and was followed by Grace Wilder, Albertini, Mrs. Bradt, and a host of other slowly improving kinds, until the list of aspirants for a place on the carnation stage reached well up into the hundreds.

Daybreak, originated and disseminated by Simmons of Geneva, Ohio, was one of the best and most profitable carnations of its day, which is now over, and was probably one of the progenitors of the fine variety Enchantress and other kinds having the Daybreak shade of pink. William Scott was another easily grown and useful sort, but it, too, is now eclipsed.

While the carnation is not a native of this continent, certain writers speak of the varieties now in cultivation here, collectively, as the American carnation; but a better term would be the American varieties of carnations, as they nearly all originated here.

At the Royal Show, held at Newcastle-on-Tyne, England, in 1908, and practically open to all exhibitors, many vases of British carnations were shown, having, in the main, stiff stems, and large flowers; but the flowers were nearly all of coarse texture, and the most of them had split calyces. Decidedly the finest carnations in the great show were those of American origin.

ORNAMENTAL SHRUBS AND TREES.

A subscriber wishes to know what trees to plant for ornamental purposes on his ranch that will bloom for sometime, as does the oleander. So many shrubs are in bloom for a short time and then are done bearing for another year. He also wishes to know what varieties are suitable to the district about Lindsay, Tulare county, varieties that will stand some frost and the heat of summer, and that will not require much irrigation; also the most ornamental varieties of acacias and eucalyptus. We give a partial list in the following:

Eucalyptus.

Probably the most ornamental eucalyptus is the Ficifolia with its great clusters of crimson flowers, but we question as to its doing well in the San Joaquin valley.

Amygdalina var. angustifolia is a very ornamental variety, rather dwarf in habit, not exceeding fifty feet in height in old age. It has very narrow leaves which are ornamental.

Eucalyptus cornuta is a more rapid grower and forms a much larger tree. Its timber is also valuable.

Polyanthema, Australian beach, produces a most valuable timber and a profusion of flowers which are of great value to beekeepers. This is the largest mentioned, acquiring a height of 150 feet.

Acacias.

Acacia floribunda is perhaps one of the best of the acacias for the conditions given. It blooms for a long time and the flowers are sweetly perfumed. It is not a large growing tree.

Cassia artemisia is a blue foliaged shrub, excellent for hedge or grouping.

Other trees which will prove fairly well adapted to the conditions named are:

Eugenia myrtifolia, Australian bush cherry, is a fair sized tree with beautiful shiny green foliage and is very graceful in habit of growth.

Of the pittosporums there are fifteen different varieties growing in California, all useful as ornamental shrubs; one or two varieties grow to large trees. All are evergreen.

Arizona ash is one of the very best deciduous trees grown on the Coast. It makes a rapid and systematic growth, is erect in habit, and is so hardy that it is recommended for hillside forest covering, standing the hottest and driest of desert climates. It has been found valuable as a timber tree.

Lonicera tataricia, or tree honeysuckle, is a fine shrub.

Swansonia grayana, the Darling river pea, is a most desirable everblooming plant. Its flowers are rose-color and produced in sprays of from twelve to twenty flowers each, the individual blooms resembling the sweet pea. The leaves are small and acacia-like. A similar plant is the Swansonia galegifolia alba, excepting that its flowers are pure white.

Hypericum moserianum has long, slender, much-branched stems, leaved to the base, all drooping toward the ends, produces freely flowers of large size measuring two or more inches in diameter, in color a rich golden yellow and rendered more effective by the yellow stamens and crimson anthers. These plants bloom continuously. Another hypericum with single yellow flowers is the yellow patulum, or St. John's wort. This does exceptionally well in dry heat and will stand a minimum of irrigation.

Plumbago capensis may be trained as a bush or does fairly well as a climber. Flowers are light sky-blue, verbena shaped, and produced during the entire summer. Stands drouth or water and the brightest of sunshine.

Entomology and Bees

BEE DISEASES.

The honey bee annually produces a crop of honey valued at least at $20,000,000, and there are vast opportunities for increasing this output. The most serious handicap to bee keeping in the United States is the fact that there are contagious diseases which attack the brood of the honey bee. There are now recognized two such diseases, known as American foul brood and European foul brood. From data recently obtained by the United States department of agriculture, it is known that American foul brood exists in 282 counties in 37 states, and European foul brood in 160 counties in 24 states, and it is estimated conservatively that these diseases are causing a loss to the bee keepers of the United States of at least $1,000,000 annually. This estimate is based on the probable value of the colonies which die, and the approximate loss of crop due to the weakened condition of diseased colonies. The states in which the diseases are most prevalent are California, Colorado, Illinois, Indiana, Iowa, Kansas, Michigan, Missouri, Nebraska, New Jersey, New York, Ohio, Pennsylvania, Texas and Wisconsin, and it is unfortunate that these are the states in which honey production is most profitable, making the future outlook of the bee keeping industry so much the worse unless active measures are taken to control the diseases. Furthermore the distribution of these diseases is by no means fully known, and they are constantly spreading.

The cause of American foul brood has been found by the department to be a specific bacterium, and enough is known of the cause and nature of European foul brood, which is also a bacterial disease, to make it possible to issue reliable recommendations concerning treatment for both diseases. Both attack the developing brood, and as the adult bees die from old age or other causes, the colony becomes depleted since there are not enough young bees emerging to keep up the numbers. When the colony becomes weak, bees from other colonies enter to rob the honey and the infection is spread.

Both of these diseases can be controlled with comparative ease by the progressive bee keeper, but the chief difficulty encountered in combating these diseases is the fact that the majority of bee keepers are unaware that any such diseases exist; they therefore often attribute their losses to other causes, and nothing is done to prevent the spread of the infection. It is therefore necessary in most cases to point out the existence and nature of the diseases, as well as to spread information concerning the best methods of treatment. Several states have passed laws providing for the inspection of apiaries for disease, and the bee keepers in other states are asking for the same protection, so that careless or ignorant bee keepers can be prevented from endangering their neighbor's bees. This inspection is a benefit in the spread of information concerning disease, in so far as the inspectors can cover the territory. The department of agriculture is helping in this work by sending out publications to the bee keepers in infected regions, by examining samples of brood suspected of disease, and by sending out information concerning the presence of disease, so that bee keepers will be informed that their apiaries are in danger. The co-operation of agricultural colleges, state bee keepers associations, and other similar agencies is urged.

In view of the fact that these diseases are so widespread, every person interested in bee keeping should find out as soon as possible how to recognize and treat these maladies, and be on the lookout for them. A publication containing a discussion of the nature of these diseases and their treatment will be sent on request to the department of agriculture.

WATER.

Bees need more water when feeding brood on old honey than on fresh nectar, and thin food, if not unreasonably thin, will induce more rapid breeding and require less trips for water. The water hunting is responsible for more spring losses than any other item, unless it be actual want of food. As the colony grows and becomes more populous, the queen will enlarge her circle, and more combs will have to be added to the room of each weak colony. If things are carefully done and a vigilant eye kept over the hives, this method is by far the most successful. The populous hives themselves may be made much more serviceable to the apiarist with a little timely feeding.

Some beekeepers may have occasionally noticed in the spring a colony or two in the apiary running over with bees, and fairly roaring with activity while the others are only slowly progressing. A close watch would have shown that these two or three colonies have had a little extra feed in the shape of stores from deceased colonies, whose condition had not been perceived in time to prevent the strong ones from robbing the little honey remaining in their combs. If such accidental feeding is productive of so wonderful results, what may not be achieved by judicious provision? After the hive is filled with brood and bees put on the sections, and if any honey is gathered it must be put in the boxes. Each section should have a small piece of comb attached to the top of it for a "starter," or be filled partly or fully with comb foundation of the thinnest make, to entice the bees to work more rapidly in them; while the center tier of sections should, if possible, be full of comb left over from the season previous. But there is another thing which plays an important part in this matter, and that is a thorough knowledge of the location we are in. In nearly all localities where bees can be kept there are certain plants which give a yield of nectar at a certain time of year, while aside from this there is a little more honey contained by the bees than is needed to supply their daily wants.—Coleman's Rural.

To be conscious of the household machinery is most unpleasant to a really good housekeeper. One of the trying things to contend with is the odor through the house of cooking. A liberal sprinkling of cinnamon on a hot stove lid or open fire entirely destroys the most disagreeable odor.

360 Egg Size
$25.00

We Pay the Freight.

"SUCCESS" Incubators

SATISFY. SIX AND ONE-HALF TIMES AS MANY SOLD THIS LAST JANUARY AS IN January, 1910. Does this not show that where one machine is tried others follow? Does it not show that poultrymen all over the West are tired of paying 25% to 35% profit to agents on Incubators, when they can buy from me at WHOLESALE. I sell to you direct; you pay no profits to agents nor false prices to concerns that sell through agents. If they sell to agents they must get a price 25% to 35% more than the Incubator or Brooder is worth. Agents must make commissions. Think it over. Get my free 48-page catalog; gives prices, and complete descriptions of every machine we make. 60 Egg Size, $9; 130 Egg, $14; 360 Egg, $25; 612 Egg, $40. I pay the freight. 75 Chick Indoor Brooder, $3; 150 Chick Indoor Brooder, $5; 150 Chick Outdoor Brooder, $6.50; Fireless Brooders. All Incubators have double walls, double packed top, paper lined throughout, automatic self-regulators, removable nursery drawers, slatted egg trays, pressed seamless lamp bowl, Sunshine Burners, kiln dried redwood only. Live Stock and Dairy

Dairymen and stockmen are requested to write of their experience. Mrs. Sherman is always willing to answer queries and this, with experience of other workers, will make this department of greater value.

CHEESE MAKING.

By M. E. Sherman.

[Owing to inquiries regarding home cheese making and a request to reprint Mrs. Sherman's articles which appeared some three years since, we give below the first; and next week will follow with another.—Ed.]

The use of cheese should be encouraged as meat is steadily advancing in price and cheese makes a good substitute for it. There is not a crumb of waste in using cheese. The broken bits are like pieces of stale bread, something that is valuable to make little appetizing additions to the family table. It is the use of these little touches that distinguish the home cooking from the hotel table. The loving little pats that are added to the food, because father, or mother or Johnny or Susie likes it. Added to macaroni or vermicelli seems to be about all the ways the average cook knows about using cheese. Try using a tablespoonful of crumbs of cheese in the ordinary flour to thicken milk dressing and put this over boiled cabbage in the pot ten minutes before serving. It makes the cabbage come closer to its cousin, the more expensive cauliflower in taste. Use the same sauce with stewed celery. In this little recipe there is a world of improvement over the ordinary white sauce.

Suggestions.

Again, add a little cheese to the celery and apple salad dressed with mayonnaise. Put the little bits of cheese on plain soda crackers with a dash of cayenne pepper and toast brown in the oven to serve with the after dinner coffee. Cheese omelet, cheese with scrambled eggs; scalloped white potatoes with the cheese white sauce are desirable acquisitions to the table. Cheese adds a tempting dainty blend to other articles used. A suspicion of fine flavor rather than actual knowledge of the contents of the dish should be the result of this blending.

Home Cheese Making.

Now that the cool weather is here there is no reason why the farmer's wife cannot from time to time make a small cheese and have it always at hand to use. It would be too bad if a careful woman cannot make as good cheese as the usual offering of California cheese at the local markets in country towns. Eastern cheese, or Swiss at a high price is usually not used by the farmer at all. If the first homemade cheese does not come out perfect in flavor for eating plain, then it can be used in cooking to advantage. The home cheese maker is more apt to fail in care in the curing than in the making.

Utensils.

These are cheap and few, compared to those used in making butter. A large, new granite dish pan can be used for a vat. Either a new wire toaster or a Christy bread knife for a cutting knife. If neither are available then use an ordinary silver table knife. Steel knives are undesirable to use, even though they be well scoured; there hangs about them a fishy, steely flavor that is not to be removed. Have a couple of tin hoops made by the tinsmith, or if you care to expend more money, the Guoda cheese hoops may be purchased in small sizes. Have the hoops ten inches across and six inches deep. Have two tin followers made that will just pass inside the hoops; have in these followers eight or ten small holes to allow the whey to escape from the cheese. A good dairy thermometer that can be put into the milk completes the outfit. Get some good cheese rennet tablets, Hansen or any other make, only do not get junket tablets, as they are not strong enough to make cheese quickly, some squares of cheese cloth; some long strips six inches wide for bandages and some ten-inch circles for tops and ends of the cheeses.

Milk.

If there is enough milk, say twenty-five gallons at a milking, use the morning's milk as soon as strained and aired. The airing is done by pouring from one pail held high to another, in a place where the air is cool and sweet. If there is not enough milk from one milking then use the night's and morning's milk. Strain the milk at night through six thicknesses of cheese cloth into a granite pan. Put the pan in a cold place covered with a piece of cheese cloth. Dust is the great enemy in California. It is everywhere; to avoid it in this milk will require care. I put the pan in a room apart and turn the key of the door so that no one walks over the floor to stir up the dust. Walking around in a clean room raises dust that may be imperceptible, yet is damaging to milk used for cheese.

Next Morning.

The next morning when the morning's milk comes in, strain it in the same manner and add it at once to the milk in the pan. Before adding the fresh milk, stir down the cream and taste the milk, to be sure it is absolutely sweet. If it should have the least suspicion of acidity do not use it for making this form of cheese, but put it into cottage cheese, or smearcase. Later, I will tell you how that is made, so if you fail to hold the milk sweet the first time there will not be any waste, only a different product from that intended. If the night's milk is sweet, then add the morning's milk and bring the pan into the kitchen. Add the coloring matter, a teaspoonful to every twenty gallons of milk, will make it a light yellow, while a teaspoonful to every fifteen gallons of milk makes the cheese a deep orange. Usually the common Eastern cheese we buy is about half way between these two amounts in color.

Cooking.

Put an asbestos mat on the stove and on it the pan of milk. Stir gently from time to time until the thermometer shows a temperature of ninety degrees; not a bit above this nor below eighty-six. Ninety is to be preferred. Stand the pan on the kitchen table and add the rennet. The rennet tablets are dissolved in a cup of cold water. The small rennet tablets are used, one for every five gallons of milk. The large-sized tablets are one to every twenty-five gal-

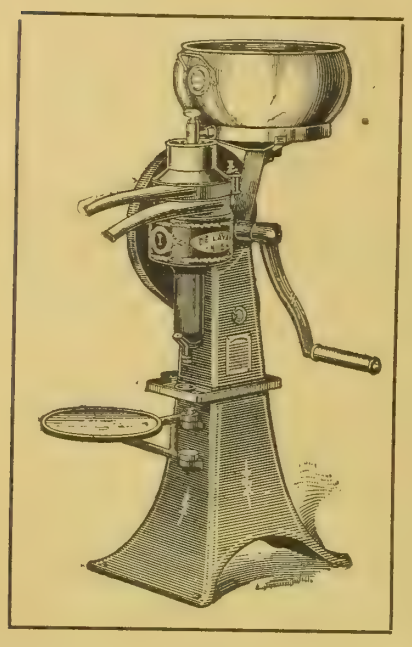
DE LAVAL and OTHER CREAM SEPARATORS

Every separator manufacturer and dealer attempting to compete with the DE LAVAL today claims his machine to be "like the DE LAVAL," "as good as the DE LAVAL," or "about the same as the DE LAVAL." Some even go so far as to falsely assert that it is licensed under DE LAVAL patents.



Their claims are true only to the extent that every one of them IS making a machine after some DE LAVAL type of ten to twenty years ago, on which the DE LAVAL patents have expired. But these copied old DE LAVAL types were either never good enough for the De Laval Company to actually manufacture itself or have been discarded by it at least ten years ago in its constant development and improvement of the cream separator.

Not a single one of these would-be imitating competing machines is in any way like the improved DE LAVAL separator of TODAY. None of them is capable of doing as good work, or being run, cleaned and handled as easily. None of them is nearly as well built or will last half as long.

There is not a prospective buyer of a separator anywhere who cannot SEE and PROVE the important difference FOR HIMSELF if he will only go to the trouble of looking up the nearest DE LAVAL agent or writing the Company if he can't find one.

It is well worth while for every intending buyer to do this. It means a saving in quantity and quality of cream and butter, time and trouble, twice-a-day, or every time he puts milk through the separator. It means a machine that will last twenty years instead of a few months or perhaps as long as five years at the outside.

It's the pleasure as well as the business of every DE LAVAL agent to explain and demonstrate the difference between DE LAVAL and other separators.

Why not take advantage of this and at least SEE and TRY a DE LAVAL before making so important an investment as the purchase of a Cream Separator?

lons of milk. Take the thermometer and test the milk. If it is between eighty-six and ninety put in the rennet. If it is not, make it right before adding the rennet. For this is a case where you have no right to do as you please, except to please to do right. Stir thoroughly, but gently, for a minute. Cover the pan with a piece of cheese cloth for twenty minutes.

Curd.

When I desire to be a certain length of time doing anything, I set the alarm on the clock and then I can take the clock with me and do some other little work. The clock calls me to the milk without waste of time in constantly watching its face. One accomplishes so much more when they guard the minutes. At the end of twenty minutes, try the curd by putting your finger gently on it and pushing sideways. If it breaks away from the mass of clabbered milk with a clean, clear cut across, it is ready for the next step. If any floating particles show in the whey when the curd breaks, leave it stand covered until the break is clean. I find the rennet varies considerably, some forming a smoothly, breaking curd in fifteen minutes and again other tablets taking thirty minutes. The directions that come printed with the tablets should be carefully read and followed. Each manufacturer has only a desire to have his goods give full satisfaction, and will give the directions accordingly.

(Continued next week.)

A NEW FROZEN DAIRY PRODUCT.

A new frozen dairy product has just been brought out by the dairy section of the experiment station at Ames. This product, which has been named "lacto," is made of loppered whole or skim milk, with the addition of eggs, sugar, lemons and flavoring materials. Lacto has a more pleasant flavor than sherbets and ices, and contains considerably more nutriment. It contains as much protein as ice cream, less fat and more acid.

In an experiment in which 179 persons sampled lacto, 128 pronounced it very good, 37 good, 6 fair, and 8 poor. Comparing it with common vanilla ice cream, 111 reported that they preferred lacto, 9 considered it equal to ice cream, and 59 preferred the ice cream. Comparing lacto to sherbet, 123 preferred lacto, 30 preferred sherbet, and 26 considered lacto equal to sherbet.

Scientists have found that there are large numbers of putrefactive bacteria in the intestines, which are very injurious and may even shorten life. Metchnikoff, the famous Russian scientist, claims that old age is the result of a slow poisoning caused by these bacteria. He recommends the drinking of sour milk, so as to replace the harmful putrefactive bacteria by lactic acid bacteria, which are harmless. The trouble with this remedy is that few people like sour milk. To provide these lactic acid bacteria in a more palatable form was one of the reasons for introducing lacto. The lactic acid bacteria are not killed by freezing, and if lacto is eaten frequently enough there is every reason to believe that these bacteria will replace the more harmful ones in the intestines. This will result in improving the health and prolonging life.

The milk to be used in the manufacture of lacto is prepared in a similar manner to the starter which is used for cream ripening. A commercial lactic acid culture is used. This is added to a pint of skimmed milk which has been pasteurized at a temperature of 85 degrees C (185F) for 20 minutes, and after pasteurization cooled to from 20 to 22 degrees C (68-71F). The lactic acid culture is thoroughly mixed with the milk and left at 20 degrees C (68 F) until the milk has coagulated. Then another bottle of skimmed milk is pasteurized and cooled in the same manner, but instead of the commercial culture, a part of the coagulated milk is added to insure the souring of the milk inside of eighteen hours. This operation is repeated until the final batch of soured milk obtained has lost the undesirable flavor due to the substance in which the commercial culture was preserved. After this point has been reached, which requires from four to six days, the last sample of soured milk obtained is added to a larger amount of pasteurized skimmed milk. This is then treated the same as the former lots. In this way an amount of milk sufficient to work with is obtained.

Lacto can be made in the household on a small scale without buying a commercial starter. Take a bottle of good clean fresh milk which has not been heated, and set it away at a temperature of from 68 to 70 degrees F until it coagulates. If it coagulates as a smooth solid curd without pinholes, if the aroma is clean and pleasant, and the flavor nice and creamy, it can be used as a starter for a larger amount of whole or skimmed milk.

The milk when ready to be used for lacto has a mild clean acid flavor. The curd must be thoroughly broken up. This is accomplished by pouring it from one pail to another until it is as smooth and velvety as rich cream. From this "lacto milk" the various lactos are prepared.

One of the most popular kinds of lacto is cherry lacto. This is prepared from the following formula, which is sufficient for 5 gallons of the finished product:

3 gallons lacto milk
9 pounds sugar
12 eggs
1 qt. cherry juice, or concentrated cherry syrup
1½ pints lemon juice

The sugar is first dissolved in the lacto milk. The eggs are then prepared. The whites and yolks are kept in separate containers and each lot is beaten with an egg beater. Both the yolks and whites are then added to the milk. The mixture is thoroughly stirred and strained through a fine wire gauze. The fruit juices are added last. If there is any indication of the juices precipitating the casein, they should be left out until the mixture has begun to freeze. The freezer is run until it turns with difficulty, when the paddle is removed. The brine is removed and the freezer repacked with ice and salt and left for an hour before the contents are served.

Additional details regarding lacto, and other recipes for its manufacture, are given in Bulletin 118 of the Iowa Experiment Station, which may be obtained free by writing to the Director at Ames, Iowa.

PASTURE FOR THE SOUTH.

We received not long since an inquiry regarding Bermuda grass, Lespedeza and Johnson grass as crops for pasture in the South. We wrote the Louisiana Experiment Station in regard to these grasses, and have received the following reply from the Dean and Director, W. R. Dodson:

"I beg to say that I consider Bermuda grass our best pasture grass. A

Warranted to give satisfaction.

GOMBAULT'S
CAUSTIC BALSAM

A safe, speedy and positive cure for

Curb, Splint, Sweeny, Capped Hock, Strained Tendons, Founder, Wind Puffs, and all lameness from Spavin, Ringbone and other bony tumors. Cures all skin diseases or Parasites, Thrush, Diphtheria. Removes all Bunches from Horses or Cattle.

As a HUMAN REMEDY for Rheumatism, Sprains, Sore Throat, etc., it is invaluable.

Every bottle of Caustic Balsam sold is Warranted to give satisfaction. Price $1.50 per bottle. Sold by druggists, or sent by express, charges paid, with full directions for its use. Send for descriptive circulars, testimonials, etc. Address

THE LAWRENCE-WILLIAMS COMPANY, Cleveland, Ohio.

Charges for Soil Work

Charges for work, for a limited time only, and subject to advance without notice:

	Per Sample.
Mechanical Analysis (4 to 5 grades of fineness)	$1.50
Lime (Available)	1.00
Magnesia (Available)	1.00
Potash	2.00
Phosphoric Acid (Soluble in weak acid)	1.00
Nitric Nitrogen	1.00
Black Alkali	1.00
Chlorine	1.00
Adequacy of Humus	1.00

Work will be done in the order of receiving the samples.

When called to make field examinations charges will be $5.00 per day from the time of leaving Los Angeles to time of arrival here in returning, and expenses.

Consultation free where five dollars' worth of work is done.

LLOYD R. TAYLOR, Modesto, Cal.

combination of white clover and Bermuda is better for cattle and hogs than Bermuda grass alone. I do not know of any conditions that would deter me from the use of Bermuda grass where the pasture is to be permanent or even to be used for several years and then used in a system of rotation. Bermuda grass sod can be turned under in the fall and planted to a very early spring crop that is cultivated, like corn, and then planted in cowpeas, and the Bermuda grass will be almost completely exterminated.

"Lespedeza and Bermuda grass make a very good combination for pasture. There is some difference of opinion as to whether or not the pasture is improved by Lespedeza. It is my personal judgment that it is. There are a few soils in which the Lespedeza will crowd out the Bermuda, but this is not the general rule.

"There are no sections in Louisiana in which Kentucky blue grass can be profitably grown, so far as my knowledge goes.

"I have never recommended Johnson grass as a crop to be planted. Where people have it already on their lands, I think it is sometimes advisable to use it for hay. Otherwise I would shun it absolutely."—Hoard's Dairyman.

QUANTITY AND QUALITY OF MILK INHERITED SEPARATELY.

It is the common opinion that cows which give a great deal of milk give milk rather low in fat content, and the reverse, that cows which give but little milk, yield milk containing a high percentage of fat. The probable foundation for this opinion is the fact that the Holsteins, which are noted for the large quantity of milk, give milk of rather low fat content, while the Jerseys, which are noted for the quality of their milk, are not especially strong on the quantity. From this it might be inferred that quality and quantity of cows' milk are opposing characteristics which are rarely joined in the same animal.

Statistics obtained from the records of several thousand Ayrshire cattle in Scotland indicate that the quantity and the quality of milk are inherited separately. That is, that a cow giving a large quantity of milk is just about as liable to give at the same time rich milk as a cow giving a smaller quantity. Of the cows giving less than 500 gallons a year, the largest percentage of them were giving milk testing around 3.8 per cent, while the largest percentage of those giving over 700 gallons a year tested in the neighborhood of 3.7 per cent. This would indicate that in the Ayrshire breed at least, a cow which is giving the large quantity of milk is just about as likely to be giving milk of high fat content as a cow giving a smaller quantity.—Wallace's Farmer.

Plenty of exercise is important for the pregnant sow; it should be insisted upon, and provided in the way the breeder finds best adapted to his situation. A large pasture is not always available, but the breeder may secure results by arranging the house at one end of the hog lot and the feeding floor at the other end, or by giving the sows water in such a way that to procure it they will be compelled to walk some distance a number of times each day.—From Coburn's "Swine in America."

Hogs are waste savers. A farm without hogs has many leaks.

CITRUS SPECIAL.

Next week's issue of the Cultivator will be devoted almost entirely to consideration of topics of special interest to citrus growers. It has been the custom for several years to devote the last issue in the month of February to the greatest one factor in California's fruit industry, which yearly brings to this state over $30,000,000. Fresh deciduous fruits bring practically $8,000,000, dried fruits, including prunes, $15,000,000, olives and olive oil nearly $1,000,000, and canned fruits nearly $10,000,000. By this it will be seen what the citrus industry of this state means to its welfare. While every issue of this paper contains something of interest to this great industry, it is worthy of having one issue almost entirely devoted to it.

Features will be articles by G. Harold Powell, who has recently come from Washington to take charge of the Citrus Protective League, Citrus in Butte County, Citrus in Tulare County, Citrus in Arizona, Pruning, Fertilizing and other points of special interest.

An interesting question has been brought out by a letter sent in by Mr. Nathan W. Blanchard of Santa Paula, a simple one in itself, but possessing large interest. Mr. Blanchard's question is as follows:

"I submit to you a question which is an interesting one in itself, and which I would be very glad to have light upon if I can get it, namely: Will the character of oranges grown from wood produced by budding into lemon stock, which is itself a growth from budding into orange stock, be influenced by the lemon wood, say from two to three feet from the lemon stock between its own bud and the orange bud?

"Some years ago many lemon trees were budded over into oranges. These lemon trees were presumably grown on orange roots, so that some of your readers are able, doubtless, to answer the above question.

"The early orange growers will remember that oranges grown on Chinese stock or roots were very coarse and could easily be recognized."

This has been sent to a number of citrus growers, and some answers have already been received. Any grower who has not received a mail request, who may have observed the behavior of buds under similar conditions, will confer a favor upon many readers if he will take this as an invitation to give us his experience.

EXTRAVAGANCE.

We don't know that the California farmer has occasion for resentment, but surely the Kansas and other Middle West farmers, whose bankers have refused to loan money for the purchase of automobiles, have, and, so far as we can learn, they have freely expressed their resentment. Most of them will admit that there has in some cases been cause for the bankers' attitude, but it is unjust for the entire class to be subjected to petty oversight because a few have become extravagant and have mortgaged their lands and gone beyond their depth. Of course, every money interest must look to its security, but to treat the farmer like a spoiled child has no justification.

There was imported into the United States last year $47,000,000 worth of diamonds, and this enormous amount, to which it has increased annually from $14,000,000 in 1900, is locked up in these gems, and with no return excepting to the vanity of the owners. Now, if the country can wear diamonds to the extent of such an enormous purchase, surely the purchase of automobiles may be permitted without dictation.

The wisdom of automobile or diamond purchase must, of course, depend on circumstances. Most grievous blunders have been committed along both lines, but that the being a farmer is justification for placing the decision in the hands of a banker—in the mind of the farmer—is the humiliating feature.

A BIG LITTLE INDUSTRY.

With a half billion dollars a year to the credit of poultry products in the United States, this industry, which is despised by many because of its smallness, reaches a magnitude which should command respect. In the year 1899 the total value of barley, rye, buckwheat, flax, broom corn, rice, kaffir corn, grapes, all small fruits, all orchard products, sugar cane and sugar beets, raised in the United States was less than the earnings of poultry. Another great product of the country is wool, yet its value is less than one-third that of poultry and eggs. The egg output alone is of higher value than all the aggregated gold and silver produced in the country.

The time was when this great industry was only the merest side issue with most farming operations. It is still on many ranches, the fowls gathering their own subsistence as best they can. Now in many sections poultry raising has become a distinct industry in which great capital is invested, and it is given the closest attention and care.

There are a half hundred periodicals devoted exclusively to the business, and no farm paper and but few of the dailies but gives some space to it. In addition, the state experiment stations, agricultural colleges, the United States Department of Agriculture, and many other agencies are joining in spreading information as to conducting this business. There are some sections which are given over almost exclusively to it, but on the other hand it may be said that there is no industry which is so widespread as this. California is importing millions of dollars worth of poultry products, yet the conditions here are almost ideal for the encouragement of the industry. It must be admitted that we have not the advantage of cheap feeds which may be secured in the Middle West, but all other conditions are perfect, especially the one of advantageous market. No section of the United States offers such prices as California has on the average for many years. Kansas puts up the boast over us that its output of poultry products is greater than that of California and Wisconsin combined, yet Kansas is the fifth in yield of eggs of the states of the Union.

Preservation of wild life is the effort of the League of American Sportsmen. It is now calling attention to the slaughter of birds through the use of the automatic shotgun. The circular calling attention to the havoc played by these automatic guns is made more forceful by the use of illustrations showing hundreds of wild geese killed as the result of one hour's work with two automatic guns. The league will endeavor to secure in every state the passage of a bill which "shall make it unlawful to use in hunting birds or animals of any kind any shotgun holding more than two cartridges at one time or that may be fired more than twice without reloading."

NEW CLUB IDEA.

The Oklahoma Agricultural College has organized a new idea in farmers clubs, which may be suggestive to some of California's farmers' organizations. It is:

"Every agricultural community should have an Acre Club. Get a number of interested farmers together and have each one cultivate one acre for the coming season so as to produce as nearly a perfect crop as possible. Each man should select a different crop, and keep an account of the preparation of the soil, the manner of planting and cultivation, date of planting and of harvesting. He should also itemize the total cost of producing the crop, and compute its value at the time of harvesting. Then, some time during the summer, there should be picnics made up of the farmers and the families who belong to these clubs, one at the home of each member. After the dinner the men should get together and talk over their experiences with their acres; they should compare notes and offer such suggestions or criticisms as seem most feasible."

OUR CREED.

We maintain that farming is, and should be, one of the most dignified professions in the world, and that the American farmer is the hope of this nation. We believe that the farmer is of more importance than the farm, and should be first improved; that the skillful hand and cultured mind are his greatest assets; that the boys and girls are his most valuable crop. We would kindle among our readers an ambition for more intelligent farming, and would make not only better farms but better homes, better men and women, boys and girls.—Minnesota Dept. of Agri. News.

We note the program of the Illinois State Horticultural Society which is holding its meeting at Champaign, Illinois. In addition to the usual discussions as to horticultural topics, there is an extensive exhibit of horticultural products. The strongest feature is the flower and plant show, the former under the direction of the Illinois State Florists Association, the plants being exhibited by members of another society. By the way, the program gives a wider interpretation of the word "horticulture" than is usual in California. California horticultural conventions have given attention almost exclusively to the commercial side of horticulture, or at least to commercial horticulture; in Illinois more attention in program and exhibits is given to the artistic. Of addresses on the program some are: Floral Decoration, Park Legislation, Development of the Public Park in the Small Town, Greenhouse Management in Home Gardens, Usefulness of Native Trees in Public Grounds, Street Trees. In addition, time is given in the program to Pruning Grape Vines, Commercial Strawberry Culture, Illustrated Pruning, Home Vegetable Garden, and other like topics.

We have referred before to the Oregon Horticultural Society exhibits, and believe the exhibit feature and the widening out of the program to take in topics of a more artistic nature is wise. It may be said that the farmers clubs and smaller organizations can handle these topics—which is perhaps true—but we believe that with our state attracting tourists from all over the world the creation of beauty is a valuable asset.

Montana ranchers report heavy losses from sheep dying in the snow.

Agricultural News Notes of the Pacific Coast

Northern California

Dealers are offering hop growers of Santa Rosa contracts for 1911 crop at 16 cents.

The apple growers association of Sebastopol, Sonoma county, proposes to incorporate.

The Western Fruit Jobbers Association is holding its sessions in Sacramento this week.

Nurserymen all report stock of olive trees exhausted owing to great demand this season.

Congress has appropriated $20,000 for an Indian Industrial School at Guinda, Yolo county.

The acreage of wheat and barley in the Sacramento valley is materially greater this year than last.

Apple growers near Petrolia, Humboldt county, realized $2.25 per box from last season's output.

Dairymen and farmers of Ferndale are planning for a bigger and better agricultural fair next September.

The total number of acres burned over in this state during 1910 is 482,563. In 1909 the total was 357,269.

The January rainfall in the Sacramento Valley was the greatest recorded. In some sections it totalled 10.64 inches.

Land owners between Hamilton and Grimes are planning for extensive planting of sugar beets for the factory at Hamilton.

The California Development Board has maintained extensive exhibits at the Land Show in Omaha during the last few weeks.

San Francisco in particular and all the state in general are rejoicing over the assurance of San Francisco being chosen for the fair location.

Pear and grape growers of Concord, Contra Costa county, will make an especial fight on thrips and hope to bring their crops up to normal.

A new rule has been put into operation on the Produce Exchange Board of San Francisco eliminating sales of butter which will not pass inspection.

Sections near Willits, Mendocino county, are proving themselves adapted to apple culture and extensive plantings are being made this season.

Frank Snow of Petaluma states that the poultry town shiped during the year 1910, 7,288,215 dozen eggs. This was a slight increase over the year 1909.

Sutter county is feeling the impetus in the almond industry caused by the organization of the California Almond Growers Exchange and is planting very extensively.

Sutter county vineyardists announce next season's output of wine grapes will be materially shortened. This is due to the grafting over of many vineyards to Thompson Seedless.

The Enabling Act to provide coin for the Panama-Pacific exposition has been introduced in the legislature and it is announced that the $5,000,000 from the bond issue will soon be available.

The Petaluma egg exchange at its recent annual elected directors for the coming year: A. LeNoir, Frank Riddell, W. Harris, Theodore King, L. A. Bittman, Harry Pinger, W. Thomas, J. Carmody and William Bassett.

Central California

A dairyman at Tulare reports having received in his cream checks for 1910, $1352.75 from fourteen cows.

With deciduous nursery stock slightly cheaper than usual incentive is given for more extensive planting.

The annual demonstration train service just closed has called out the biggest attendance ever given in this valley.

The raisin men feel very hopeful that the new co-operative marketing concern being formed at Fresno will prove a success.

Demonstration in the inoculation of Berkshire hogs with hog cholera serum was made at Hanford at time of visit of the demonstration train.

Hatfield, the "rain maker," is given "credit" for the great precipitation of the state. He is now planning to go to London and obliterate its fogs.

Quite an extensive experiment made last year on various islands of the San Joaquin river delta gives hopes of the successful culture of hemp in this state. Over 200 acres will be planted this season.

The Port Watsonville beach, Santa Cruz county, is said to possess the finest clam beds in the world, but owing to the great drain upon them during the last few months, it is feared they may be soon exhausted.

The Strobridge bill, which has been signed by the governor, has abolished the office of county statistician. The office was created largely to aid the state board of agriculture in the securing of state statistics.

The irrigators of Fresno, Madera, Merced, Stanislaus and San Joaquin counties met recently in the city of Madera and advanced the cause of the great irrigation district which will cover nearly 2,000,000 acres of the West Side.

The Santa Cruz County Poultry Association was addressed at its last monthly meeting by the manager of the National Egg Company of San Francisco. It is hoped a large egg packing plant will be constructed in that city soon.

The 5,500-acre state redwood park in Santa Clara and Santa Cruz counties has been removed from the management of the state forester by a bill duly signed by the governor, and is now placed under control of a special commission of five to serve without salary.

The Modesto and Turlock irrigation people are pleased at the passage of Senator Griffin's irrigation bill, which provides for a commission composed of the attorney general, the state engineer and the state controller, this commission to have power on application of the board of directors of any proposed district to report on feasibility of any irrigation plan.

The fruit growers association of Lockeford, San Joaquin county, has elected officers for the coming year, as follows: Henry Inglis, president; S. S. Strobridge, vice-president; Peter Deitderich, W. S. Montgomery, H. J. Bruml, F. Figgee and Charles Knudsen. Henry Inglis, Peter Deitderich and F. Figgee were elected to succeed S. A. Wheelock, T. R. Burkett and W. S. Allen of the old board.

Southern California

Sugar beet planters have already begun seeding beets in many sections.

The Anaheim Water Company reports the most successful season in its history.

Los Angeles is planning for a Land and Products Show to be held during the entire month of March.

Spotting of oranges has continued and succeeded in depressing the market materially in all parts of the East.

A state citrus growers convention is to be held in San Bernardino during the week of the National Orange Show.

Cotton growers of the Coachella Valley are talking of introducing a cotton picking machine in time for next season's picking.

Perris, Riverside county, is still working for the establishment of a sugar factory and hopes are daily growing brighter.

San Bernardino is making great preparations for her National Orange Show which is to take place the week beginning March 6th.

Several experiments in avocado growing at Whittier are proving very successful and quite extensive plantings are promised this season.

The San Luis Rey creamery near Oceanside, San Diego county, paid 41 cents per pound for butter fat during the last four months of 1910.

The Redlands Y. M. C. A. has established a school of horticulture, occasional lectures being given by some of the best specialists in fruit growing in the state.

The work of enlarging the great Sweetwater Dam at San Diego is nearly completed. The storage capacity of the dam when completed will be 11,572,000,000 gallons.

The Palo Verde Mutual Water Company is making more liberal rules as to delivery of water and encouraging more general settlement of the land of that rich section.

Work on the Anaheim sugar factory is proceeding rapidly, even some of the machinery being already in place. The coming season will find complete readiness for beets.

The Escondido Valley in San Diego county has an attack of the "chicken fever" and is now claiming that it will soon be one of the principal poultry sections of the state.

One Imperial valley cotton grower is to try the experiment of growing cotton in a field with barley, leaving the barley as a protection from sun and hot winds while plants are young.

Citrus growers are keeping their eyes upon the situation in congress and upon the misstatements which are apearing in eastern magazines regarding the so-called excessive tariff on lemons.

The orange picking stopped by the continued rains of the first of the month was nicely resumed when the storm of last Saturday stopped work again. Prices in the East are fairly satisfactory.

Desert claims in the Chucawalla Valley, Riverside county, are rapidly being improved and many thousand acres have been cleared ready for water which it is hoped may be secured from the Colorado river near Parker.

The Coast

Hydrophobia has become epidemic at Wallowa, Oregon, and sheep, cattle, dogs and coyotes all are affected.

One potato grower at Twin Falls, Idaho, produced a crop of 645 bushels on one acre and won a $500 prize.

Tacoma, Washington, market shows a shortage of practically all kinds of fruit, even apples being exhausted.

Over 100,000 acres of land will be put under irrigation in Southern Idaho by a project now under way at Weiser.

The grange at Bellingham, Washington, is appealing for more attention for agriculture in the schools of the state.

Oregon farmers are holding their wheat rather than sell at present quotations. Dealers in Portland report supply nearly exhausted.

Missoula, Montana, has a new country life club. Its first work is in discussing landscaping and otherwise beautifying the farm home.

A heavy fall of snow has covered the wheat fields of the Inland Empire in Western Washington. Some sections record over fifteen inches.

Ex-President Roosevelt will take part in the dedication exercises of the great Roosevelt dam in Salt River Valley, Arizona, March 10.

Owners of 6,000 acres of land near Weston, Oregon, have raised a fund for preliminary surveys looking to the formation of an irrigation district.

Producers of Alaska will make exhibits at the American Land and Irrigation Exposition to be held at Madison Square Garden next November.

The people of Yuma, Arizona, will make extensive exhibits of agricultural products at the coming land show to be held in Los Angeles March 18 to April 2.

The legislature of Washington has changed its good roads law so that state road funds are now under the direction of county supervisors in connection with the state engineer.

The fourteenth annual session of the Montana Agricultural Society was held in Missoula last week. The next session will be at Great Falls. The new president is C. C. Willows, of Plains.

The Salt Lake demonstration train which touched various points in Nevada and Utah was given a royal reception, some of the towns greeting the train with closed stores and brass band reception.

Land owners near Weiser, Idaho, recently held an election, voting almost unanimously for the formation of an irrigation district, and voting for bonds for $150,000. Waters will be taken from Crane creek.

At the last meeting of the Idaho State Horticultural Association the proposition was made to form a fruit growers marketing and distributing agency. A committee was appointed, to report at a later special meeting.

The state convention of fruit growers at Boise, Idaho, passed a resolution establishing a standard for all apples of the state, grading into two classes, fancy and choice. Demonstrations of methods of packing and requirements of different grades were given at the convention.

Practical Poultry Culture

SUCCESS IN THE POULTRY BUSINESS.

It's no wonder that a few fail in the poultry business. In every kind of business we find that some are not successful, so in the poultry business it is not the fault of the business itself, but of the individual.

Most every one that prospers in the poultry business (and those that go into it, who are progressive and stay by it, do prosper) will tell you that they like poultry and take great interest and pride in their fowls and read poultry papers and are doing a better business all the time.

The first reason for failures is that some start into the business too heavy and not understanding the business have more than they can manage. It is better to begin small and grow big, as you learn more about the business. When I began I started with a flock of thirty, but I made one bad mistake; I did not start with pure bred stock. I realized my mistake at once and began right by getting pure breds and keep no other kind and increase my flock and the facilities for easy work, too, each year.

At the same time I bought some pure bred eggs one of my neighbors started into the poultry business. He bought a trio of show birds, paying an enormous price for them, when for the money he spent he could have gotten three dozen good, pure bred fowls of the same kind, which would have been, perhaps, better for breeding purposes. He had a few mongrels and instead of keeping his pure bred hens laying when they wanted to set, he let them set and each bring up a litter of chickens that summer. That fall when he did not yet have any more chickens than he needed he carried off his trio to a show. He did win some prizes, but his cock and one hen contracted roup and died, and his entire little flock had a bad spell of roup. He built some fancy and expensive houses and brooders, too, when plain ones would have done. He has never sold a fowl or egg. Poultry business has been a failure with him. Is it any wonder? While he has failed, consider the many, many people who have started in with a little pure bred flock and prospered.

Second. Many fail because they do not read the poultry papers. I have heard many poultry raisers say, "Oh, them editors don't know anything about poultry." They don't know that most poultry editors have been poultry raisers at some time in their life. I can say that I have learned as much about the poultry business by reading the poultry papers as I have from experience, for the fact of the matter is, I practically knew nothing about the business only in a haphazard way until I began reading poultry papers. Am taking four good ones all the time and would not be without them. About 99 per cent of all successful poultry men read and study poultry papers and good poultry literature.

Third. Some fail because they do not know how to advertise.

If you have only a small flock it's not necessary to carry a whole page advertisement, like the large breeders, for you can sell all you have from a smaller advertisement. While on the other hand, no matter how good or large your supply, others will not know it unless you tell them by means of poultry papers and show exhibitions.

Another thing about advertising is to be real honest and not claim your stock is one whit better than it really is. Better to lose a few sales than have any dissatisfied customers.

Fourth. Some are too easily dissatisfied. They do not study their breed and how to make it better, and when they see some one else with a different kind doing better they sell off and buy some other kind. I have a relative who has been in the chicken business for eight years and has had about sixteen different kinds of fowls. Within the past two months he has been selling off good, high-scoring Black Langshans at the ridiculous price of $4 a dozen and buying Dark Brahmas at top-notch prices. He sold off Light Brahmas, Leghorns, etc., in years past in just the same way. About February, 1911, he will not be getting eggs when everyone else is and he will have the blues. He ought to learn that it takes years to build up a good winter laying strain and that it takes constant care, too. No doubt before spring opens up he will be changing to some other kind. He will tell you he is a great poultry fancier and has tried poultry business until he is almost discouraged, for there's no money in the business. There isn't for him, either.

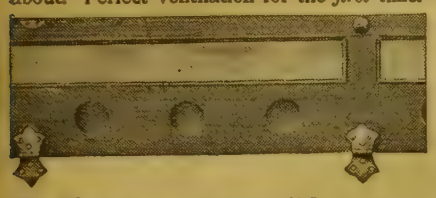
Fifth, some start with too many varieties. For the farmer or anyone not devoting all their time to the business, one kind of fowl is enough. If you raise one kind and aim to make it better, and to have your customers pleased, you will have plenty to do to raise enough birds of your kind to supply the demand.

Sixth. Some are too anxious to make sales, and rather than lose a sale will sell inferior stock. If you have not what your customer wants, send his money back and say so. You will make more in the long run. No matter how good the stock you have, there will be many young fowls that are not show birds and some that are not good enough even to sell for breeding purposes. These culls should be weeded out. Either sell them to the groceryman or butcher or eat them at home. My family are very fond of fried chicken. We eat fried chicken every other day the year round, selecting birds that we see are not going to have the best of color, plumage, shape, etc. Thus we get rid of the culls and find them very cheap meat, too. Never market a soiled egg either, put all such in a separate basket and use them in your own kitchen. In fact, make it a point to have your customers well pleased.

Seventh. Some fail because of lack of attention to the little things. A sick chicken, allowed to run about, a few varmints permitted to harbor, may bring disastrous results. Longfellow says, "Serve yourself if you would be well served," or in the poultry business if you look after the details of the work and the little things, you will know that the work is well done. The raising of one's feed, though only a small matter, is very profitable too. The ground in the colonies being turned over and sown in wheat or clover is a small matter but will prove very profitable, is not expensive and is better than all the poultry tonics in the world. Having

More Inventions by Lee

Here's his new Incubator door all are talking about. Perfect ventilation for the *first* time.



Mandy Lee Incubators

supply life-giving oxygen freely to the eggs and just as naturally draw off the poisonous gases. The most important step ever taken in incubator ventilation—neither above nor below, but *right at the eggs*—the correct principle, for the new Mandy Lee is making better hatches of *stronger* chicks than any other incubator in the world.

We Measure Everything

Heat—moisture—ventilation. You *guess* at nothing. If the eggs are good and you follow simple directions your work with a Mandy Lee is as nearly an absolute certainty as anything can be. There is no more reason why you should buy an incubator that regulates nothing but heat than for a farmer to continue to harvest his crops by methods and machinery used 100 years ago. Your success with poultry depends on your ability to select equipment that is *right*—that's what you *always* get from us.

No guessing with a Mandy Lee

Send *to-day* for new catalog. Learn of these new improvements and of our new *out-door*, *lamp-heated* and *regulated brooder*, just what is needed.

the coops, hen houses, fences, etc., all arranged so as to be the most convenient and make the work easy and save time, seems to be a small matter to most people. One great thinker and writer has said, "Do not squander time, for that is the stuff that life is made of." And in making hen houses, coops, etc., so as to be convenient, right here is where the papers help again, for many useful things about making useful and convenient hen houses, the best floors, etc., are discussed.

In conclusion, then, I say that when anyone fails in the poultry business, it's all on account of the individual and not the business.

There never was a time when the market prices for poultry and eggs were so good. There never was a time when there was such a demand for good pure-bred stock of all varieties, or kinds. There never was a time when poultry papers, journals and poultry literature could be had at such a small cost, or when they were as good either, for every editor is ambitious and wants to make his paper the most helpful in the world and wants to get as large a subscription roll as possible, in order to advertise well for his customers.—Harvey I. Burdick in monthly prize article in Am. Poultry Journal.

HEALTH OF TURKEYS.

When we consider the good prices at which turkeys sell it is surprising how few farmers there are who try to grow them, says Mrs. B. F. Wilcoxon, in the Fruit-Grower. It is only on the occasional farm where turkeys are raised, where the managers take good care of them and know their peculiarities, and these make the business a profitable one. Many do not keep turkeys because of their inclination to wander away from home, which is one of their wild characteristics that has not been thoroughly bred out of them. This is a matter that is not wholly within the control of the turkey growers. If they are managed properly there will not be such a tendency to wander away. If they are fed properly and at regular intervals about the barn and premises they will not be likely to wander away except at nesting time and when insect life is most abundant. On many farms no roosting-place is provided for turkeys, and they are compelled to shift for themselves, and the inclination is to seek proper roosting places, which may lead them away from the buildings where they belong. Turkeys do not do well when confined, therefore roosting places indoors will not answer. It is better to supply them some place out of doors, either in a grove or on the sheltered side of some building that is more open. If open sheds are provided where nothing can disturb them they will go there the worst days during the winter when sleet and snow make them seek shelter. A turkey seems to enjoy the branches of a tree. Turkeys seem to require indulgence in their wild habits, and when they have been turned too widely from that environment they are prone to disease. For this reason it is a matter of economy to compel turkeys to live as near to nature as possible, or to the same requirements as the orignal wild turkey, in order to get the best result.

Turkeys keep in better health when they are permitted to wander about the premises and obtain a good deal of their food themselves. As scon as they are housed and are permitted to feed and drink with other fowls, roup or some other fatal disease claims a number of them. One of the great drawbacks to growing turkeys in domesticity is that of practicing inbreeding, and yet in their wild state there is nothing to prevent it. The wild turkey we all know seldom has disease. In domestic life, where inbreeding is practiced, disease claims many young turkeys. In view of this condition it is therefore safest to procure breeding stock unrelated. I am inclined to believe that the damage they do to grain and other crops in their rambles is slightly overestimated by those who do not own turkeys, and believe the amount of good they do in picking up bugs, worms, beetles, etc., is somewhat underestimated.

Turkeys are possibly the choicest fowls that can be taken to market, and invariably bring the highest prices. Success will depend very much upon the favorableness of the season for hatching and rearing. The turkey, of all fowls, is possibly the one that requires the most care and attention during the first few weeks following incubation. Then the birds are very delicate and very susceptible to all variations of temperature. Rainy or foggy weather is fatal to them, and it is not to be wondered at, therefore, that the percentage of mortality is so very high with young turkeys. I use a great many calomel tablets in raising young turkeys. If you are losing turkeys hold a post mortem and examine the organs very carefully. In nine cases out of ten you will find the liver to be covered with yellow spots. These tablets will, if properly used, bring relief.

A great many people make the mistake of feeding too heavily. The little poults need to be fed often and a little at the time. Your poults require care similar to little chicks, only more of it. Guard against chill and dampness. Be shy of overfeeding the first week. Supply grit and water as for chicks. Feed bread crumbs for the first week or two, gradually working cottage-cheese into the bill of fare. Let them have the run of a good grass lot in pleasant weather, where they can get plenty of bugs and grasshoppers. As they get older let the mother run with them in the grass through the day. As turkeys are seed-eating fowls I now rely on the mixed seeds sold on the market. These contain grit also. I often mix black pepper in their soft feed. By midsummer they will have learned where the best bugs and weed seeds are to be found and care very little for the food that you have to offer them. But try to induce them to roost at home by giving them a liberal feed at night. No other class of poultry will forage so well through the summer and autumn. No other will so rapidly transform insects and weed seeds into the best flesh.

Turpentine is deservedly a popular remedy for worms in turkeys. Give about a teaspoonful to a fowl, followed by a dose of a teaspoonful of a solution of Epsom salts.

In mating turkeys, one gobbler to ten hens is sufficient. Turkey eggs while being saved for incubation should be kept at an even temperature of fifty or sixty degrees. If temperature is not extreme either way it is not of so great importance as the frequent turning of the eggs. Turn them at least one a day—twice a day is better—and keep them covered from the light and dust. If good care is taken of the eggs they will keep for three weeks and hatch well. The turkey is our Thanksgiving and holiday bird, therefore sell before or directly after these seasons if you expect to obtain the best price for them.

Go In and Make Money

Poultry offers the surest, easiest way of anything that's open to you. Don't waste *all* your time considering. Go in and *make* it win.

SUCCESSFUL TURKEY-RAISING.

For the average farmer the Bronze is perhaps the best breed, possessing as they do hardiness with large size. Breeding stock should be the best specimens of the preceding year; the characteristics of these will be transmitted to the flock of this season, writes Mrs. A. C. McPherson, in Successful Farming. It will be of benefit to introduce new blood after a season or two, but still many of our successful breeders retain males for years, with no apparent diminution of vigor in progeny.

When the hen turkey begins wandering around and peering into clumps of bushes, holes, etc., searching for nesting places, it will save time, trouble and eggs if she is placed in some outbuilding and kept there until she lays, nesting places being provided of course. Generally, if the nests are hidden or secluded enough to suit their fastidious fancy they will return to the nests of their own accord and continue to do so until the laying season is over. If the weather is cold it is best to remove the eggs at evening lest they should chill. But one or two should be replaced in the morning. They will generally lay from twenty to twenty-five eggs before showing a desire to set. If not desirable to allow them to do so they can be confined and fed liberally, and all desire to brood will pass away in a short time. When one has but few turkey hens this will prove the best way and will secure more eggs for incubators later in the season, or at the end of the second clutch of eggs the hen turkey may be allowed to sit.

We have been successful in discarding the turkey hens and employing chicken hens for brooding purposes instead; hens possessing an abundance of fluffy feathers and of quiet habits being preferred. The turkey hen is wild and strolling by nature, and requires extra care if she is expected to rear a reasonable per cent of her brood.

Generally twenty-seven days are required for incubation, but we have had broods come off on the twenty-fifth day when the weather was warm and favorable, although they have been known to be delayed until thirty-one days, so it is best not to be hasty in destroying the unhatched eggs until certain that all are hatched that will ever be. It is a good plan to examine the unhatched eggs and note their appearance. We can learn a great deal in this way, and if the eggs were bought the breeder will want to know about the hatch, if good, why, etc. Many breeders replace infertile eggs at half price. This is an item, particularly when paying the present prices which reliable dealers demand. Place as many eggs in the nest as the hen can cover well, and no more.

Free the hen from vermin by dusting with insect destroyer (pyrethrum), holding the hen by the feet so as to insure the powder being well-settled among the feathers. This matter of vermin is an important one, for upon it hangs very much of the success of rearing the poults. Should vermin be upon the mother hen they attack the poults and soon cause them to droop and die. Lard and kerosene mixed may be applied to the mother hen but not to the young poults. Pyrethrum should be dusted on them whenever there are signs of the enemy. These signs will be drooping wings and a dejected air generally. An examination of the wings will disclose such a case—vermin teeming among the wing-feathers, drawing the life-blood from the innocent victims. Keep the hens quiet during the hatching and do not allow them to be disturbed. If the hens remain quiet it is better not to remove the newly hatched poults, but if they become restless remove the poults and put them in a warm place. There is more uniformity in the appearance of the turkey poults than the young of any other fowl, and if they are of one breed or kind the poults are as much alike as peas in a pod.

After all are hatched let the hen off for a while for exercise. Then place her and her brood in a coop that is clean and free from vermin, place on short grass and remove to a fresh spot daily. The poults require no food until a day old, as nature has provided for them, but water and sand should be placed within reach. The food should not be of a sloppy kind, as that leads to bowel trouble. Curds or Dutch cheese is liked by them and they thrive on it. Stale bread, moistened and squeezed dry, is good. Onion tops and dandelion leaves minced fine should be fed each day while in confinement. Corn bread is the best food when two weeks old, and later cracked corn or wheat should be provided. If wire runs are used much of the trouble connected with their raising will be avoided, and they should be restricted to the coops and runs until about two weeks old; then they may be allowed out a few hours if the day is fine, but should not become fatigued. The hen should not be allowed to wander around until the poults are on the point of exhaustion. The young turkey is delicate and the poulterer should have a knowledge of their wants and requirements in order to bring them safely through their minority, or the first few weeks of their lives. After that it is comparatively smooth sailing, for as soon as the red appears they suddenly become hardy and are able to care for themselves and take to the grain fields or woodlands as naturally as a duck to water. At this interesting stage of their lives it is to the owner's profit to see that all flocks are rounded up at night; and in order to induce regularity, grain should be fed in the evening on their return. The fatality among young turkeys in nine cases out of ten is caused by want of due care during the earliest stage of existence. Low or wet grounds, in fact any dampness, induces rheumatism of joints, etc. Given dry, clean quarters, suitable feed and freedom from vermin, the turkey is as easily reared as any other poultry.

Turkeys are excellent gleaners and what would otherwise go to waste in distant grain fields is utilized.

From the first plaintive "Peep! peep!" of the poult until the "Gobble! gobble!" of the mature turkey is a comparatively short period, and each stage is watched with interest by the careful owner or breeder.

"Dry-picking is always to be preferred when preparing turkeys for market. When in fine condition, nicely picked, and sent to market without having been packed in ice, a turkey is at its best, and consequently commands the highest price. As soon as the fowl is stuck, while the blood is still flowing, pluck the feathers dry from its body, taking care in doing this not to break the skin or tear the flesh. Nothing detracts so much from dressed poultry as torn places upon the carcass or shank; picking must be clean and nicely done. When the fowl is plucked hang it head down in a cool place until all animal heat is gone from the body. Do not remove the head, feet, or entrails, but have the whole carcass, including head and feet, perfectly clean."

When rabbits are plentiful it will pay to buy them for the chickens. Skin them and hang them up in the poultry house and the hens will soon pick off all the meat. If you can shoot the rabbits yourself, all the better. You will be destroying a nuisance on your farm and supplying a delicacy to your chickens.

FREE—The Largest Book of Its Kind Ever Printed

64 Pages—Every Breed Illustrated

and many other interesting pictures taken from life in and around Southern California. This book is the largest and most expensive ever printed by any concern whatsoever on baby chicks, hatching, etc., etc. Tells the prices of every breed of chicken, turkey, goose, etc., that we offer for sale. Tells how we ship thousands and thousands of baby chicks safely year after year, and gives full details on the raising of baby chicks, hens, etc. Articles on every part of the chicken business are given, and it won't cost you but ONE CENT—just a post card—saying you want it.

Laying hens, PULLETS, COCKS, COCKERELS, BABY CHICKS, HATCHING EGGS, COLONY HOUSES, INCUBATORS, BROODERS, etc. Investigate—that is all we ask. Send today. We mail at once. Send the names of anyone near you that is interested in poultry. We will be glad to mail the books.

Articles under each of the following heads: "Color of Baby Chicks," "Thoroughbreds," "Poultry Pays," "Does It Pay to Buy Baby Chicks?" "Fireless Brooders," "We Ship Chicks in Fireless Brooders," "When to Go Into the Poultry Business," "There Is Money in Eggs and Poultry," "Will the High Prices Last?" "Baby Chicks Ship Safe," "A Chick in the Hand," "Who Can Enter the Poultry Business," "Poultry Business Open to All," "Poultry Raising by Disabled People," "Broilers for Market," "Your Opportunity," "How to Start," "Where to Start," "Poultry for Market or Eggs," "Little Capital Required," "Vitality in Poultry," "Poultry Successes," "Keep Chicks Warm,," "Opportunities in the Chicken Business," "Get Started Right," "As a Side Line," "Order Early," "How Shall I Start?" "About Prices," "Stock and Eggs," "Egg Farming on the Colony Plan," "How to Care for Baby Chicks" (2 pages), "Good Layers," "Our Own Flock of White Orpingtons," "The Best Breed," "Combining Poultry and Small Fruit," "Eggs From Pure Stock," "Poultry and Specialty Vegetable Growing," "Pure Bred Stock," "Thoroughbred Males," "Poultry Shows." These are the headings of the articles we write for you free. If the book is worth one cent just say you want it on a post card. No book of its kind has ever been printed. It's the largest of its kind ever printed anywhere by anyone. Get a copy. Visitors welcome always.

Eggs For Hatching

Trapnested S. C. White Leghorn Eggs

$1.00 per Fifteen or $5.00 per Hundred

H. A. CARPENTER, Yuba City, Cal., R.R. No. 1., Box 52

Rancho Mirasol White Leghorns

Eggs for Hatching, January to June. Day Old Chicks, March to June.

PASADENA, CALIFORNIA.

Coulson's

MADE IN PETALUMA

Special chick food

If nature hatches the egg, you should save the chick. And you can do it with Coulson's Special Chick Food—the greatest life-saver known in the chicken industry.

This food is the result of years of study to get just the right ingredients in a proper mixture to save the largest possible number out of every 100 chicks.

Coulson's Special Chick Food is an investment, not an expense. It pays big dividends by starting chicks on the road to profit for you. Costs about one cent a chick for four weeks' feeding.

Coulson's Growing Chick Food must be used after the first six weeks, to keep up the steady growth of the chicks up to three months, at which time they are old enough to use Coulson's Egg Food—the standard feed for laying hens.

At your dealer's or from us. Write for the interesting book, "Poultry Feeding for Profit." It's free.
